Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

when
extrapyramidal
symptoms upset
phenothiazine
therapy

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/cc

COGENTIN®
(BENZTROPINE MESYLATE | MSD)

helps keep productive therapy from becoming counterproductive

- Helps relieve rigidity and tremor
- Provides long duration of action
- Frequently permits continuation of the phenothiazine without change of dosage

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per cc, in 2-cc ampuls.

For more detailed information, consult your MSD representative or see the Direction Circular. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

Here's what a group of anxious psychoneurotics (most with associated depressive symptoms) looked like after Valium® (diazepam) and psychotherapy

Pretreatment evaluations were compared with those of the second and fourth week of treatment, yielding a cumulative "improvement" score for each patient, symptom and observation interval.† A global assessment of the patient's emotional status was also made at each rating period.

Psychiatric Evaluation on a Modified BPRS*	Average scores of 17 patients—out of initial group of 21 patients—in study for 26 or more days**				
	Not present	Very mild/ mild	Mod- erate	Moder- ately severe/ severe	Extremely severe
1. Somatic concern	1	2	3	4	5
2. Anxiety	1	2	3	4	5
3. Emotional withdrawal	1	2	3	4	5
4. Guilt feelings	1	2	3	4	5
5. Tension	1	2	3	4	5
6. Depressive mood	1	2	3	4	5
7. Hostility	1	2	3	4	5
8. Motor retardation	1	2	3	4	5
9. Blunted affect	1	2	3	4	5

†With the exception of excessive anxiety and undue tension, the signs and symptoms shown in the Modified BPRS are not in themselves indications for Valium.

Valium® (diazepam) Tablets
Complete Prescribing Information:

Description: Valium (diazepam) is a benzodiazepine derivative developed through original Roche research. Chemically, diazepam is 7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one. It is a colorless, crystalline compound, insoluble in water and has a molecular weight of 284.74.

Pharmacology: In animals Valium (diazepam) appears to act on parts of the limbic system, the thalamus and hypothalamus, and induces calming effects. Valium (diazepam), unlike chlorpromazine and reserpine, has no demonstrable peripheral autonomic blocking action, nor does it produce extrapyramidal side effects; however, animals treated with Valium (diazepam) do have a transient ataxia at higher doses. Valium (diazepam) was found to have transient cardiovascular depressor effects in dogs. Long-term experiments in rats revealed no disturbances of endocrine function.

Oral LD_{50} of diazepam is 720 mg/kg in mice and 1240 mg/kg in rats. Intraperitoneal administration of 400 mg/kg to a monkey resulted in death on the sixth day.

Reproduction Studies: A series of rat reproduction studies was performed with diazepam in oral doses of 1, 10, 80 and 100 mg/kg. At 100 mg/kg there was a decrease in the number of pregnancies and surviving offspring in these rats. Neonatal survival of rats at doses lower than 100 mg/kg was within normal limits. Several neonates in these rat-reproduction studies showed skeletal or other defects. Further studies in rats at doses up to and including 80 mg/kg/day did not reveal teratological effects on the offspring.

In humans, measurable blood levels of Valium (diazepam) were obtained in maternal and cord blood, indicating placental transfer of the drug.

Indications: Valium (diazepam) is useful in the symptomatic relief of tension and anxiety states resulting from stressful circumstances or whenever somatic complaints are concomitants of emotional factors. It is useful in psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation.

In acute alcohol withdrawal, Valium (diazepam) may be useful in the symptomatic relief of acute agitation, tremor, impending or acute delirium tremens and hallucinosis.

Valium (diazepam) is a useful adjunct for the relief of skeletal muscle spasm due to reflex spasm to local pathology (such as inflammation of the muscles or joints, or secondary to trauma); spasticity caused by upper motor neuron disorders (such as cerebral palsy and paraplegia); athetosis; and stiff-man syndrome.

Oral Valium (diazepam) may be used adjunctively in convulsive disorders, although it has not proved useful as the sole therapy.

Contraindications: Valium (diazepam) is contraindicated in patients with a known hypersensitivity to this drug and, because of lack of sufficient clinical experience, in children under 6 months of age. It may be used in patients with open angle glaucoma who are receiving appropriate therapy, but it is contraindicated in acute narrow angle glaucoma.

Warnings: Valium (diazepam) is not of value in the treatment of psychotic patients and should not be employed in lieu of appropriate treatment. As is true of most preparations containing CNS-acting drugs, patients receiving Valium (diazepam) should be cautioned against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving a motor vehicle.

As with other agents which have anticonvulsant activity, when Valium (diazepam) is used as an adjunct in treating convulsive disorders, the possibility of an increase in the frequency and/or severity of grand mal seizures may require an increase in the dosage of standard anticonvulsant medication. Abrupt withdrawal of Valium (diazepam) in such cases may also be associated with a temporary increase in the frequency and/or severity of seizures.

Since Valium (diazepam) has a central nervous system depressant effect, patients should be advised against the simultaneous ingestion of alcohol and other CNS-depressant drugs during Valium (diazepam) therapy.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of diazepam (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). These were usually limited to those patients who had received excessive doses over an extended period of time. Particularly addiction-prone individuals (such as drug addicts or alcoholics) should be under careful surveillance when receiving diazepam or other psychotropic agents because of the predisposition of such patients to habituation and dependence.

Use in Pregnancy: Use of any drug in pregnancy, lactation or in women of childbearing age requires that the potential benefit of the drug be weighed against its possible hazard to mother and child. (See *Reproduction Studies.*)

Management of Overdosage: Manifestations of Valium (diazepam) overdosage include somnolence, confusion, coma and diminished reflexes. Respiration, pulse and blood pressure should be monitored, as in all cases of drug overdosage, although, in general, these effects have been minimal following overdosage. General supportive measures should be employed, along with immediate gastric lavage. Intravenous fluids should be administered and an adequate airway maintained. Hypotension may be combated by the use of Levophed® (levarterenol) or Aramine (metaraminol). Ritalin (methylphenidate) or caffeine and sodium benzoate may be given to combat CNS-depressive effects. Dialysis is of limited value. As with the management of intentional overdosage with any drug, it should be borne in mind that multiple agents may have been ingested.

Precautions: If Valium (diazepam) is to be combined with other psychotropic agents or anticonvulsant drugs, careful consideration should be given to the pharmacology of the agents to be employed —particularly with known compounds which may potentiate the action of Valium (diazepam), such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The usual precautions are indicated for severely depressed patients or those in whom there is any evidence of latent depression; particularly the recognition that suicidal tendencies may be present and protective measures may be necessary. The usual precautions in treating patients with impaired renal or hepatic function should be observed.

In elderly and debilitated patients, it is recommended that the dosage be limited to the smallest effective amount to preclude the development of ataxia or oversedation (2 mg to 2½ mg once or twice daily, initially, to be increased gradually as needed and tolerated).

Adverse Reactions: Side effects most commonly reported were drowsiness, fatigue and ataxia. Infrequently encountered were confusion, constipation, depression, diplopia, dysarthria, headache, hypotension, incontinence, jaundice, changes in libido, nausea, changes in salivation, skin rash, slurred speech, tremor, urinary retention, vertigo and blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances and stimulation have been reported; should these occur, use of the drug should be discontinued.

Because of isolated reports of neutropenia and jaundice, periodic blood counts and liver function tests are advisable during long-term therapy. Minor changes in EEG patterns, usually low-voltage fast activity, have been observed in patients during and after Valium (diazepam) therapy and are of no known significance.

Dosage and Administration: Dosage should be individualized for maximum beneficial effect. While the usual daily dosages given below will meet the needs of most patients, there will be some who may require higher doses. In such cases dosage should be increased cautiously to avoid adverse effects.

Adults:	*USUAL DAILY DOSE*
Symptomatic Relief of Tension and Anxiety States and Psychoneurotic States.	Depending upon severity of symptoms—2 mg to 10 mg, 2 to 4 times daily
Symptomatic Relief in Acute Alcohol Withdrawal.	10 mg, 3 or 4 times during the first 24 hours, reducing to 5 mg, 3 or 4 times daily as needed
Adjunctively for Relief of Skeletal Muscle Spasm.	2 mg to 10 mg, 3 or 4 times daily
Adjunctively in Convulsive Disorders.	2 mg to 10 mg, 2 to 4 times daily
Geriatric Patients, or in the presence of debilitating disease.	2 mg to 2½ mg, 1 or 2 times daily initially; increase gradually as needed and tolerated
Children:	
Because of varied responses to CNS-acting drugs, initiate therapy with lowest dose and increase as required. Not for use in children under 6 months.	1 mg to 2½ mg, 3 or 4 times daily initially; increase gradually as needed and tolerated

How Supplied: For oral administration: Valium (diazepam) scored tablets—2 mg, white; 5 mg, yellow; and 10 mg, blue—bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Book Review Editors: Alfred H. Rifkin, M.D., and Leon Salzman, M.D.

The *Journal of the American Academy of Psychoanalysis* is devoted to the psychoanalytic exploration of man in the broadest possible sense without adherence to the tenets of any one school. It is a journal open to anyone with a contribution to make in this everexpanding field.

The purpose of the *Journal of the American Academy of Psychoanalysis* is to develop communication among psychoanalysts and their colleagues in other disciplines in science and in the humanities, constitute a forum for inquiry into the phenomena of individual motivation and social behavior, encourage and support research in psychoanalysis, foster the acceptance of psychoanalysis and its integration in universities, and advance the interests of psychoanalysis in all other respects.

PARTIAL CONTENTS OF FIRST ISSUE

Science, Psychodynamic Reality and Autistic Thinking—*Harry Guntrip*
Developmental Aspects of Psychological Disturbances—*Kenneth Keniston*

See next page for brief summary.

EMOTIONAL WITHDRAWAL
CONCEPTUAL DISORGANIZATION / ANXIETY
TENSION / HALLUCINATORY BEHAVIOR
SUSPICIOUSNESS / BLUNTED AFFECT

One or more of these symptoms in a schizophrenic is an indication for

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

Before prescribing, consult package circular.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Serax®

Her signs and symptoms suggested it – Your complete workup confirmed it.

noticed that palms were moist

said she lost interest in most things

thinks she has a "nervous stomach"

said she was tired and listless most of the time

Clinically significant anxiety may manifest itself by a variety of signs and symptoms, all of which are more readily apparent than those of depression. As a result, the coexisting depression that so frequently exists is often overlooked.

Many such patients are being treated with just a tranquilizer and nothing more. This can complicate or expose the underlying depression and even delay symptomatic improvement.

That's why an obviously anxious patient should be given a thorough evaluation with a complete history and physical examination.

If coexisting depression is affirmed, the physician should consider a medication specifically formulated to aid in treating the anxiety-depression syndrome.

TRIAVIL is that kind of agent.

Indicated for moderate to severe anxiety with depression, TRIAVIL is a dual component product consisting of perphenazine, a highly effective tranquilizer *and* amitriptyline HCl, an effective antidepressant. Working together, these two components treat *both* anxiety and depression, often relieving many of the somatic complaints so commonly associated with this disorder.

The drug may impair alertness and can potentiate the response to alcohol. Should not be used during the acute recovery phase following myocardial infarction. Should not be given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. Contraindicated in CNS depression and in bone marrow depression. Suicide is inherent in any depressive illness. Close supervision of patients is essential until satisfactory remission has taken place. This type of patient should not have easy access to large quantities of the drug.

For a brief summary of prescribing information, please turn to the following page.

A FLEXIBLE TRANQUILIZER-ANTIDEPRESSANT
FOR MODERATE TO SEVERE ANXIETY WITH DEPRESSION

TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

CONTAINING PERPHENAZINE AND AMITRIPTYLINE HCl
FOR MANY PATIENTS WITH
MODERATE TO SEVERE ANXIETY WITH DEPRESSION

TRIAVIL® 2-25: Each tablet contains 2 mg of perphenazine and 25 mg of amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains 2 mg of perphenazine and 10 mg of amitriptyline HCl.

TRIAVIL® 4-25: Each tablet contains 4 mg of perphenazine and 25 mg of amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains 4 mg of perphenazine and 10 mg of amitriptyline HCl.

INITIAL THERAPY
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

IN MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible. Elevation and lowering of blood-sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood-sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

THE OUTSIDER

The newly discharged mental hospital patient—outside the protective hospital environment, and facing a world filled with uncertainties

Integration into community life is likely to be the most difficult hurdle the newly discharged patient has to face. For patients with psychotic disorders, continued medication is often basic to an outpatient treatment program that bridges the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can participate more fully in the entire therapeutic program. (Even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, minimal extrapyramidal stimulation—notably pseudoparkinsonism—is a distinctive feature of Mellaril.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *CutaneousReactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Behavior of Chimpanzees in Their Natural Habitat

BY JANE VAN LAWICK-GOODALL, PH.D.

In his search for the biological basis of human behavior patterns, the scientist finds a fruitful resource in studying the chimpanzee, man's closest living relative. The author describes some of the findings from a longitudinal study of chimpanzees at Gombe, Tanzania; these concern the long period of infant and juvenile dependence on the mother, the affectionate bonds in the chimpanzee family, adolescence, and dominance. She also discusses some of the behavior patterns of chimpanzees that strikingly resemble some patterns in man, noting, however, that there are also important differences that point up the uniqueness of the human.

IN 1960, AT THE INSTIGATION of the late Dr. L.S.B. Leakey, I began a longitudinal study of free-living chimpanzees (*Pan troglodytes schweinfurthi*) in the Gombe National Park, Tanzania, East Africa. This park comprises a narrow stretch of rugged, mountainous country running for some ten miles along the eastern shores of Lake Tanganyika and inland three miles or less to the tops of the peaks of the rift escarpment. The rift is intersected by many steep-sided valleys, which support permanent streams. In the valleys, riverine gallery forest is found; between the valleys the slopes are often more open, supporting deciduous woodland. Many of the higher ridges and peaks are covered only with grass. The area supports a population of between 100 and 150 chimpanzees.

This chimpanzee population is divided into communities of individuals who recognize and may interact with each other. Within such a community, which may include up to 50 or so individuals, chimpanzees mostly move about in small temporary associations, the membership of which is constantly changing as individuals or groups of individuals split off to move about alone or to join other associations. These groups may be all males, they may be females and youngsters, or they may be combinations of different age-sex classes. Chimpanzees, especially males, often move about quite on their own.

Some individuals in the community meet only when attractions, such as a local abundance of food or a female in oestrus, happen to draw them together; others meet more often; and some show strong bonds of mutual attraction and associate very frequently—traveling, grooming, feeding, and resting together. A mother and her dependent offspring is the one association that may remain stable over a period of years, though such a family unit frequently moves about with other associations.

In the wild, chimpanzees probably always live in male-dominated societies. Individuals of a community who frequently associate show a fairly well-defined dominance hierarchy, while among chimpanzees who meet only seldom the relative social status may be less clear-cut. As yet there is little information on relationships between individuals of different communities, but we do know that at least some chimpanzees may penetrate the home range of a neighboring community and peacefully travel, feed, or mate with its members.

Chimpanzees are promiscuous in that a female, during oestrus, may be mated by many males and no stable pair-bonds are formed. However, young females in particular may move with the same adult male (sometimes possibly copulating exclusively with him) during successive periods of oestrus (1).

Chimpanzees are omnivorous, feeding mainly on a variety of plant materials, especially fruits, but also consuming many insects, occasional bird's eggs or fledglings, and sometimes actively hunting and killing medium-sized mammals.

These apes follow no set route, day after day, in their search for food. Within a fairly large home range (which may be 20 square miles or more) they are nomadic, sleeping close to where dusk finds them. They typically move on the ground when traveling, although they do spend a good deal of time in the trees both during feeding and at night. They construct quite elaborate nests for sleeping: each individual typically makes a new nest every night, except for youngsters of up to five or six years (sometimes older), who share one with their mothers.

This is an edited version of the Adolf Meyer Lecture, read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Van Lawick-Goodall is Scientific Director, Gombe Stream Research Center, Tanzania, East Africa, and Visiting Professor, Department of Psychiatry and Program in Human Biology, Stanford University Medical Center, Stanford, Calif. 94305.

In the wild, a female chimpanzee does not give birth until she is at least 12 or 13 years old, and she has only one infant every four or five years. Life expectancy in the wild is not yet known but is probably between 40 and 50 years. The longevity record for a captive chimpanzee is about 47 years.

From 1963 onward, observations of social interactions between the different individuals of the nomadic community were considerably facilitated by the establishment of an artificial feeding area where bananas were offered to chimpanzees passing by. This attraction of the chimpanzees to a specific area has enabled detailed longitudinal records on the behavior of approximately 70 different individuals of both sexes and all ages. Since 1965, a growing team of investigators has been contributing to the understanding of the behavior of the Gombe Stream chimpanzees. Hugo van Lawick has built up a unique documentary film and still-photograph record of their behavior.

The need for a study extending over a great many years is due not only to the fact that the chimpanzee has a long life expectancy, or that there is a fairly high mortality rate (due mainly to disease and injury), but also to the fact that these apes are highly individualistic, differing markedly from one another in behavior as well as appearance. Thus a great many individuals must be studied in depth, through as much of their life cycles as possible, before one can make meaningful generalized statements about chimpanzee behavior. The understanding of individual differences is, in fact, one of the principal aspects of our research.

SIGNIFICANCE OF CHIMPANZEE RESEARCH FOR UNDERSTANDING HUMAN BEHAVIOR

The chimpanzee is man's closest living relative. Recent biochemical research has already revealed striking similarities in, for example, the number and form of the chromosomes, the blood proteins, immune responses, and DNA (2, 3). Neuroanatomical research has shown that the structure and circuitry of the chimpanzee brain is closer to that of the human brain than is that of any other living primate. Behavioral research, in the field and in the laboratory, has highlighted remarkable similarities in this sphere also. Taken together, these findings suggest that, at some point in the distant past, man and chimpanzee shared a common ancestor. If this is true, we may assume that characteristics shared by modern man and modern chimpanzee were present in our stone-age ancestors.

Field studies provide information on the ways in which the structure and behavior of the species in question are adapted to its environment. Thus, since the chimpanzee is man's closest relative, and since he lives in an environment similar to that in which early man is thought to have emerged, an understanding of his behavior may well shed new light on the behavior of early man. This is of utmost significance to those concerned with human evolution—those who are trying to understand how and why man has become what he is today. As Hamburg (4) has pointed out, some aspects of our behavior today—for example, our tendency toward violent action—seem unsuitable for the world in which we now live. Such tendencies, however, were undoubtedly shaped, over millions of years, to ensure the survival of our ancestors in a very different kind of world—a world that was in all probability far more like the world of the chimpanzee. We desperately need a greater understanding of aggression in man, and an appreciation of its evolutionary history and significance would be quite helpful.

Laboratory studies of the chimpanzee, under controlled conditions, can be very meaningful in understanding some aspects of human behavior. This ape is the best experimental model for those investigating human mental disorders. It is possible, for instance, to create in a chimpanzee a condition resembling human psychosis or one closely similar to some human depressions (5). But in order to work in a meaningful way toward a cure for the depressed or psychotic chimpanzee subject, it is essential to have access to a wealth of background knowledge concerning the normal behavior of the species and the conditions under which abnormal behavior is likely to develop.

Finally, increasing scrutiny of chimpanzee behavior is likely to pinpoint crucial areas in need of careful study in human subjects. Compared with human society, chimpanzee society involves extremely simple cultural traditions. The individual chimpanzee expresses his underlying motivations in a relatively straightforward way, with little masking of his responses. Thus it will be possible to tease out the biological roots of certain aspects of chimpanzee behavior despite its complexity; it may then be rewarding to reexamine the behavior in question in man to see whether similar factors may be involved.

SOME SIGNIFICANT LONG-TERM FINDINGS AT GOMBE

I should first like to outline some of the interesting findings that our longitudinal study is revealing, particularly those relating to the different stages of the life cycle in wild chimpanzees.

Period of Infant and Juvenile Dependence on the Mother

One of the striking findings to emerge from the study at Gombe is the length of the period of infant and juvenile dependence on the mother. The infant relies completely on his mother for food, transport, and protection until he is at least six months old. He may then take his first unsteady steps and begin to ingest minute amounts of solid food. However, riding on the mother continues to be his normal method of getting from place to place until, sometime in the fourth year, he begins to make increasingly longer journeys under his own steam. Milk continues to be his major source of nourishment for at least two years and possibly longer.

Youngsters are not finally weaned until their fifth or sixth year in most instances. The youngest to be weaned, to date, was four and a half years old; one, about six and

a half years old at the time of this writing, is still not finally weaned. Juveniles may continue to sleep in a nest with their mothers after being weaned. Usually they start sleeping in their own nests during their sixth or seventh year; this often coincides with the birth of a younger sibling.

During the final stages of weaning, a young chimpanzee may go through a period of apparent depression during which he frequently reverts to earlier forms of infantile behavior such as clinging to his mother during travel and maintaining much closer contact with her than previously. His frequency of play is likely to decrease at such a time, and he may appear listless and apathetic.

These symptoms were especially pronounced in one youngster, Flint, the son of a very aged female, Flo. Flint was weaned early, at four and a half years, toward the end of his mother's pregnancy. He went through a period of depression, as outlined above, during which he constantly solicited social grooming from Flo and, when she rejected any of his other demands (e.g., wanting a share of her food), was likely to fly into wild tantrums, screaming and hitting the ground—even, on occasion, attacking his mother. When the new infant was born Flint recovered somewhat: he stopped riding Flo's back, pestered her less, and in general seemed more lively (though he did continue to push into his mother's nest each night with his infant sister). A few months later, however, he once more became lethargic, once more demanded constant grooming, and reverted to riding his mother's back even though the new infant was clinging beneath. These symptoms showed no signs of abating until, when she was about six months old, Flint's sibling died. After this Flint became much more active, but he has remained abnormally dependent on his old mother and is still, at the age of eight years and three months, sleeping in her nest. He has traveled about without Flo for more than an hour or so only on very rare occasions.

Similar symptoms of depression have appeared in other five- and six-year-olds for a few months immediately following the birth of a sibling, when they therefore no longer have first claim on the caretaking responses of the mother. In some cases this appears to be offset by the intrinsic fascination of the new baby for the juvenile sibling (6).

The significance, for the youngster, of the affectionate bond with his mother was illustrated dramatically when three individuals, all between three and four years old, lost their mothers. Two of these were "adopted" by elder siblings with whom they traveled and slept at night. But in spite of this, and in spite of the fact that they seemed well integrated into the chimpanzee society, both became increasingly listless and both showed declining frequency of play during the first few months. Subsequently the behavior of one of them, Merlin, became increasingly abnormal and he developed a number of unusual patterns and stereotypes of the kind associated with early social deprivation in the laboratory chimpanzee (7). These included rocking back and forth, hanging upside down and motionless for minutes on end, and pulling out his hairs individually during self-grooming. In addition he showed

FIGURE 1
Merlin, one year after his mother's death

Photograph by E. Koning. Copyright: National Geographic Society.

more submission and aggression and spent more time in social grooming than is normal for youngsters of his age. In some social responses and in some tool-using techniques, Merlin's behavior appeared to show some regression (6). He finally died of a paralytic disease but was so emaciated by then that it was almost certain that he would have died anyway (figure 1).

The second orphan, Beattle, was adopted by an older and more experienced female than Merlin's sister. Beattle not only traveled and slept with her sister but was also permitted to ride about on her guardian's back, a luxury denied to Merlin, who was probably too heavy for his sister. Beattle's condition gradually improved and, about a year after her mother's death, her behavior was comparable with that of other youngsters her age. We might speculate that the added social security she derived from close physical contact with an experienced, almost-adult female who knew how to behave in moments of social excitement helped to minimize the psychological shock caused by her mother's death. We cannot, however, draw any firm conclusions from so inadequate a sample.

The third three-year-old had no elder sibling and after her mother's death wandered about for the most part quite alone. She quickly became lethargic, stopped playing almost entirely, and two months after her mother's death stopped visiting the feeding area. She was not seen again and was finally presumed dead.

During its sixth or seventh year a juvenile is increasingly likely to become accidentally separated from its mother. Initially this usually results in obvious distress on

the part of the child (and sometimes on the part of the mother, too). The lost youngster starts to whimper and then scream as it scans the countryside in all directions, often from the top of a tall tree. Perhaps it is only after a series of such accidental separations that the juvenile itself finally initiates a brief bout of independent travel. The young male may start to move about in groups without his mother during his seventh or eighth year, but he does not normally spend more than a few days at a time away from her until his ninth or tenth year. The female may remain almost constantly with her mother for even longer.

The long period of dependency on the mother may be considered adaptive in the chimpanzee, as in man, in relation to social learning. In simpler forms of life, much behavior is almost entirely genetically coded, although at all levels individual experience undoubtedly plays some role in the development of behavior. But as the mammalian brain becomes increasingly complex, culminating in the brain of higher primates and of man himself, social learning plays a vastly more crucial role. The adult chimpanzee lives in a complex society: he must learn to recognize 30 or more individuals in order to react appropriately when he meets them. In addition to appreciating the status of each of these individuals in relation to his own, he must also know how the presence or absence of a high-ranking associate may affect his own or his companions' ranking in the hierarchy in a given group. Chimpanzees have an elaborate system of communication with each other, and their behavioral repertoire also includes such complex patterns as cooperative hunting and tool using. Learning undoubtedly plays a major role in the development of a youngster, and the years when he associates closely with his mother are undoubtedly to his advantage: he can rely on her to react appropriately to individuals of high or low rank, to assist him in times of stress, and to lead him to appropriate food sources. Initially, when the mother cares for his every need, the infant can direct most of his energy into exploring his physical and social environment, and even when he becomes a juvenile and must to some extent fend for himself, he can still spend much time, under the benign leadership of his mother, in gradually acquiring the skills and competences that will fit him for adult life.

It has been shown experimentally that nonhuman primates are able to learn through direct observation of the behavior of others (8, 9), and the wild chimpanzee infant certainly has much opportunity for learning of this sort. An infant often watches intently while his mother, or another older individual, is engaged in tool using, nest making, feeding, and a whole variety of social behaviors. Subsequently he may be seen to imitate the actions he has observed—either immediately, as when he picks up a grass tool just discarded by his model and endeavors to use it in a similar manner, or a short while later, as when a youngster watches an adult male performing a charging display and, when things are calm again, repeats some of the display movements himself, often in a seemingly playful context. Behaviors of this sort may be practiced time and time again. Thus, while a gradual maturation of locomotor and manipulative patterns undoubtedly plays a vital role in the development of many of the complex activities of the adult chimpanzee, it is almost certain that learning, through both trial and error and direct observation of models, is also a very significant factor (10).

Affectionate Bonds in the Chimpanzee Family

When we refer to a family in chimpanzee society, we mean a mother and her offspring of different ages, together with her daughters' offspring. There is no "father" as such. The male, after playing his role in the conception of an infant, has no further part in the raising of an offspring since, as I already mentioned, no permanent pair bonds develop between male and female chimpanzees. Our study has revealed, however, that the affectionate bonds between mothers and their offspring and between siblings are sometimes strong and long-lasting.

As we have seen, the young male associates very closely with his mother until he is nine or ten years of age. Moreover, all five of the males we observed whose mothers were alive during their adolescence continued to associate with them frequently during that period. We have now been able to make detailed observations on the relationships between three old females and their socially mature sons—that is, males more than 15 or 16 years of age. One of these females had two such sons, the others one each. All these young males associated quite frequently with their mothers, and during such times social grooming between mother and son was frequent. Moreover, on a few occasions mothers were observed to hurry to the assistance of adult as well as adolescent sons; similarly, sons occasionally assisted their mothers. Sade (11) has reported similar lasting bonds between mothers and sons in the rhesus monkey population on Cayo Santiago.

Of interest is the fact that we have not yet observed a sexually mature male try to mate with his mother. Our sample size is too small for conclusions to be drawn about this, since it involves only one mother with two adult sons and another with one. However, in one instance the mother, during four days of oestrus, was mated by every other mature male in her group with the exception of her two adult sons, who were also in the group. Some inhibition of mother-son mating has been observed in two other longitudinal studies of primate societies, Japanese monkeys (12) and rhesus macaques (13).

Females tend to remain closely associated with their mothers for even longer than males but to date we have been able to follow the development of a relationship between a mother and her daughter into the latter's adulthood in only one case; in other cases either the mother or the daughter died before the daughter became adult.

Of the five mother-daughter pairs we have been able to follow through the juvenile and at least the early adolescent period, two mothers showed affectionate and protective behavior toward their daughters similar to that described for the mother-son relationship. However, the other three mothers were far less tolerant of their female offspring than of their sons, and all three daughters showed fear of their mothers in some contexts, especially in feeding situations. Nishida and Kawanaka (14) de-

FIGURE 2

Photograph by Baron Hugo van Lawick. Copyright: Gombe Stream Research Center.

scribe two adolescent females who initially associated frequently with their mothers but who, when they became sexually receptive, began to travel about independently of their mothers for much of the time.

In the case where we have been able to document the relationship with a mother and her daughter from the latter's infancy to social maturity (the old female Flo and her daughter Fifi), the bond between the two has always been of a very relaxed and tolerant nature. In 1971 Fifi had her first infant (our major hallmark for social maturity in a female), so that for the first time we now have the opportunity to study the development of bonds between grandmother and grandson and between nephew and uncle in wild chimpanzees (figure 2). Fifi still associates frequently with her mother and youngest brother, Flint, and the relationship between these individuals is presently being carefully studied by M. Hankey.

The extension of the affectionate bond between a mother and her offspring beyond weaning means that when the mother has a new infant this youngest member of the family is likely to have a great deal of contact with his older sibling, who will usually still be semidependent on the mother. He will also have (though to a lesser extent) contact with older independent siblings during those times when they associate with the mother. Thus, as Sade (11) has pointed out, the parent-offspring relationship may ramify into other relationships of potential importance.

We have already seen that an orphaned infant may be adopted by an older sibling; this was the case even when the caretaker (of an infant of 14 months) was a juvenile *male.* This orphan was too young to survive without her mother's milk, but if we examine the three cases in which the orphans were between three and four years old we find that one of those adopted by a sister survived to become a normal youngster; the second, although he eventually died, nevertheless lived for 18 months after the death of his mother. The third, with no elder sibling, dis-

appeared and almost certainly died within three months.

Observations on two pairs of brothers suggest that long-term bonds, similar to those observed between a mother and her son, may typically be formed between brothers. Similar close bonds are found in rhesus monkey brothers (11).

To date we have been able to study the relationship between only one pair of chimpanzee sisters, the eldest of whom is close to social maturity and the other approaching adolescence. These two associate with their mother almost all the time, and the bond between all three is very close.

Other than juvenile-infant pairs, we have been able to document in detail the relationships between brothers and sisters in only three families, and these data suggest that the bonds between siblings of different sex tend to become weaker as the individuals mature. Mating does occasionally occur between brothers and sisters, but it is extremely rare. One young female (Fifi) repeatedly ran off screaming when she was first approached by her two brothers in a sexual context, although she was quick to respond to the courtship displays of other males. Eventually both brothers did achieve sexual intercourse with their sister, but thereafter they were observed to copulate with her only a few times during the two years prior to her pregnancy. One other young female was observed to be mated by her elder brother only a few times during 12 or more periods of oestrus; another adolescent female, who has been sexually receptive for over a year, has not yet been observed mating with her elder brother.

Adolescence

Adolescence is another area about which our longitudinal observations are yielding interesting information.[1] This period of the life cycle is considered by some to be solely culturally determined and therefore unique to man. However, chimpanzees (as well as most other nonhuman primates) show both physiological and behavioral changes around puberty and during the following few years; this makes it appropriate to distinguish a period of adolescence. It commences just prior to puberty (approximately eight years of age) and ends when the individual reaches social maturity (about 12 or 13 years of age in the female and some two years later in the male).

The female, as we have seen, tends to associate with her mother for an even longer period of time than the male. Since a mother is quite likely to be nursing an infant during her daughter's adolescence (and even if she is not, she will certainly associate with other females and infants from time to time), it is unnecessary for the adolescent female to leave her family group in order to gain experience concerning her future role as a mother. Some adolescent females are fascinated by small infants and spend much time playing with, grooming, or carrying them. A female with this "maternal" approach is likely to become very preoccupied with her own infant sibling. Other females seem less interested, particularly for a while after the onset of regular sexual cycling.

The female sexual cycle is characterized by menstrual bleeding and periodic swelling and deturgescence of the anogenital region. The increase in genital swelling coincides with a very marked increase of attraction and receptivity to males. The average length of the cycle is about 34 days. Maximum genital swelling averages six to seven days; menstruation occurs between six and 12 days from the start of detumescence. These swellings first appear as a very slight turgidity of the clitoris in a seven- or eight-year-old female and, with each successive month, gradually get larger. Some five to ten months prior to menarche (between eight and a half and ten years of age for captive chimpanzees, according to Asdell [15] and Riopelle [16]) the adolescent female develops a much larger swelling and suddenly becomes sexually attractive to adult males.

Females show a great deal of individual variation in their initial responses to the sexual advances of mature males. Since courtship typically comprises many gestures that occur also in aggressive contexts, some females are extremely fearful initially and may try to escape, screaming, when a male approaches for copulation. Other females seem to take sexual approaches as a matter of course.

For several months prior to her first period of receptivity, one adolescent female (Fifi) frequently remained very close to older females who showed genital swellings, apparently in order to be on hand when they were mated. She would then either jump on the back of the other female and press her own genital area as close to the male's penis as she could or else go round behind him, turn her back on him, and press her genital area against his rump during copulation. As might be expected, she was quick to respond to the slightest courtship gesture when she herself became receptive for the first time.

In many groups of nonhuman primates, exchange of genes between groups occurs when males from neighboring ranges change groups. This is well documented for rhesus monkeys (13, 17), Japanese monkeys (12), and baboons (18), and it almost certainly occurs in gorillas (19, 20). Some male chimpanzees at Gombe have sometimes been absent from the feeding area for up to two months; during such times they may have visited neighboring communities and possibly mated with their females. If that were so, however, one would expect males from neighboring communities to occasionally mingle with individuals of our habituated group, but there is no evidence that this has occurred.

Transfer of females from one group to another is known to occur occasionally among baboons (18) and among gorillas (19). Among chimpanzees, however, there is much evidence that females, principally adolescent females, play a major role in widening the gene pool. At Gombe there are a number of records of adolescent females temporarily leaving their home communities during periods of oestrus and mixing and mating with males of neighboring communities (1). In at least two cases, young "stranger" females have gradually become integrated into our community of habituated chimpanzees,

[1] Anne Pusey, a graduate student at Stanford University, is currently making a detailed study of adolescence.

although to date no habituated adolescent female has permanently left our area. Nishida and Kawanaka (14) have now recorded 39 cases of females transferring from one community to another during oestrus; the majority of these females were adolescent.

It is especially interesting to note that it is the adolescent female herself who appears to initiate the change in range; she does not normally seem to be forced to leave her home area by threatening behavior on the part of males. In our own species, it is very often the women who leave their natal groups and move to live with their new husbands in villages—or even countries—that may be quite strange to the women concerned.

Adolescence often seems to be a stressful period for the male chimpanzee. He has a growth spurt after which he tends to become more aggressive, particularly toward females. By the time he is about ten years old he is able to dominate many females who a few years earlier were themselves able to subdue him with ease. At the same time he must learn to behave with increasing caution to avoid arousing the aggression of the mature males, some of whom are quick to threaten him for behavior they tolerated when he was a mere juvenile. Nevertheless, despite the fact that he may become increasingly fearful of these older males, he often seems to deliberately choose to associate with them. Many of his first journeyings without his mother are made with adult males.

When he is with older males the adolescent tends to occupy a peripheral position in the group. He desists from sexual activity with a popular female—or at least waits for a quiet moment when the big males are resting peacefully. He sits a few yards away from a group of males who are grooming each other but usually does not dare to join them. He often feeds at a slight distance from his superiors. Yet he can often be observed watching the older males very intently.

After associating for a while with his superiors, and particularly if he has been the victim of their aggression, the adolescent male moves away from them and either travels about for a while on his own or returns to his mother if she is still alive. Indeed, his relationship with his mother may well be one of the most stabilizing factors at this time of social change for, despite his larger size and more aggressive behavior to females in general, his behavior toward her remains remarkably constant.

At some period during his adolescence, the young male may engage in a number of status conflicts if there is another male of similar age and social rank as himself with whom he associates quite frequently. These conflicts mainly involve bluff, but may sometimes lead to physical attacks. The charging display appears to have special significance in this context. This is a typically male performance that occurs in a variety of situations, principally when a male arrives at a new food source, when he meets up with other chimps after a separation, or when he is frustrated in the attainment of some goal (when, for instance, he is inhibited from feeding or mating due to the proximity of a superior male). During the display he runs slowly or very fast, on all fours or upright, with hair bristling; he may drag or throw branches, hurl rocks, sway branches, leap through the trees, or (in the case of two individuals) beat his chest like a gorilla. This display enables the performer to look larger, more powerful, and more dangerous than he may really be; it appears to be a useful technique in the acquisition of a higher social status. The more frequent and the more impressive the display, the more rapidly the adolescent may rise in the hierarchy. Since such a display only seldom involves a physical attack on a rival it is adaptive in that it enables a chimpanzee to acquire status without any great risk of injury to himself.

During the final years of adolescence the male gradually begins to threaten and occasionally attack the lower-ranking males of the adult male hierarchy. When he is able to subdue even one of them consistently he can be considered part of their hierarchy and thus socially mature.

Dominance

The past ten years of research at Gombe have brought to light some interesting facts concerning dominance, particularly with regard to those qualities which enable a chimpanzee to acquire the alpha position in his community. In 1963 Goliath, a powerful and aggressive male in his prime (perhaps about 25 years of age) was the alpha male. He had a spectacular charging display during which he covered the ground very fast indeed, dragging and occasionally hurling branches. Early in 1964, however, Goliath was displaced from his top-ranking position in the community by an older and much less robust male, Mike. Mike apparently accomplished this by means of bluff and, without doubt, superior intelligence.

In 1963 Mike was among the lowest-ranking of all the adult males, frequently threatened or even attacked by most of the others. Then he began to incorporate empty four-gallon kerosene cans into his charging displays. Other males had occasionally seized hold of such a can (from my camp area) during a display, but it seemed that only Mike was able to profit from the experience and deliberately use cans to enhance his performance. He soon learned to keep up to three cans ahead of him as he ran, very fast, hitting or kicking them along as he went. He made a great deal of noise; other males as well as females and youngsters rushed out of his way.

After charging past a group of males a few times and scattering them, Mike then sat with his hair erect; the other males, previously his superiors, approached him with gestures of submission or appeasement, crouching before him, touching, kissing, or grooming him. Mike rose to become alpha male of his community in about four months without engaging in any actual attacks on other males that we observed. He maintained that position even when we took the cans away (for we too disliked the noise) for the following six years.

Mike, in his turn, was relieved of his top-ranking position by a younger, very large, and extremely aggressive male, Humphrey. For about a year previously Mike, who was getting old, had appeared uneasy in his alpha position and was being ignored during displays by some of the younger males. Only one fight was observed between

FIGURE 3
Flo begging for meat from the alpha male Mike

Photograph by B. Gray. Copyright: Gombe Stream Research Center.

Mike and his successor, although other incidents may have occurred prior to this. Unlike Goliath, who had maintained a very high-ranking position for several years after losing his alpha rank, Mike dropped rapidly to a low position in the hierarchy. This was possibly due to the fact that at the time of the takeover, he was very much older than Goliath had been (21).

In chimpanzee society dominance is something of a conundrum. The usual interpretation of the phenomenon is that it enables a high-ranking individual to have prior access to desirable foods, females, or resting places. Competition over these resources is rare in chimpanzee society, at least at Gombe. Possibly a high-ranking position is desirable because, once an individual has attained it, he need no longer fear threat or attack from too many other chimpanzees of higher rank. Whatever the underlying motivation or ultimate reward, however, many chimpanzees do seem preoccupied with raising their social status, while others are less concerned and tend to keep out of the way during times of social excitement.

The story of Mike's rise to alpha male provides an excellent example of the way in which chimpanzees typically rely on threat or bluff rather than actual physical violence in their interactions with each other. Fights do occur, but they are generally brief; even when they appear vicious, they seldom result in observable physical injury. Moreover, after a fight the victim ordinarily approaches the aggressor showing postures and gestures that have been labeled submissive or appeasing and in response to which the aggressor usually reaches out to touch or pat or kiss the subordinate. This reassurance behavior serves to calm the agitated victim and helps to ensure generally relaxed and peaceful relationships among those individuals who frequently associate in the community (22).

SIMILARITIES IN CHIMPANZEE AND HUMAN BEHAVIOR

I have outlined various aspects of the life cycle of wild chimpanzees that it has been possible to document because of the long-term nature of our study. As knowledge is gradually accumulated about a variety of different monkey and ape species, it is possible to trace certain evolutionary trends of increasing complexity, culminating in man. Some of the data I have discussed so far clearly illustrate the high position of the chimpanzee on this evolutionary ladder. If, for instance, we take a primitive New World monkey, the marmoset, we find that infants are weaned at six months and attain sexual maturity at 14 months. The gestation period is 140 days, and estimated longevity in captivity about ten years (23). If we next take the rhesus monkey we find that weaning takes place any time between six months and a year, or sometimes a little later. The monkey is reproductively mature at about four years of age, though it does not acquire full size until about ten years. The average gestation period is 164 days and the life expectancy in captivity about 30 years (23). Now we come to the chimpanzee, where the youngster is not weaned until he is about five years old and is dependent on his mother for another three or four years, where reproductive maturity is not reached until seven to eight years in the male and (in the wild) about 11 or 12 years in the female. Moreover, the male does not become socially mature for some five or six years after puberty and is unlikely to be reproductively effective in his society until he is at least 12 years old and probably older. The longevity record is almost 50 years in captivity. In all these characteristics the chimpanzee can be seen to be very close indeed to man.

I should now like to discuss some of the behavior patterns of chimpanzees that strikingly resemble some patterns in man.

Cooperative Hunting and Food Sharing

As mentioned earlier, chimpanzees are omnivorous. They quite frequently hunt fairly large prey animals such as the young of bushpig, bushbuck, and baboons, and young or adult monkeys of various species. Sometimes the capture of prey is a very individual and opportunistic event: one chimpanzee happens upon a suitable victim, seizes and kills it, and begins to feed. On other occasions, however, male chimpanzees may hunt in a group and show behavior that can clearly be labeled as cooperation. For instance, one chimpanzee may cautiously creep up a tree toward a potential victim, such as a young baboon that has become slightly separated from its troop, while other male chimpanzees stand around the base of this tree and also near trees that might act as escape routes

clarity and becomes muddied by much foreign matter. The patients in many prior studies showed some similarities to patients in the current study, but the factor labeling among studies sometimes differed, so that what is similar can often only be guessed at. To me the confusion says that groups of men and women suffering from alcoholism have a wide dispersion of miseries, behaviors, attitudes, and prognoses. The disorder would seem to be best regarded as multidimensional rather than as a unitary illness with differing manifestations—symptoms, not yet comprising a syndrome.

Dr. Evenson and his associates plan to use this study as a base in structuring other treatment-outcome studies. I hope it won't be long before an assessment-assignment method will evolve that enables us to draw, from patients' self-descriptions, guidance toward providing an effective treatment program for this large, seriously handicapped group.

tom, behavior, attitude, etiology) would thus not necessarily be invariant across samples. An analogy might be made to studies of groups formed on the basis of fever as a presenting symptom.

In comparing the present study with studies of similar populations (4, 5), some consistencies do emerge. All three studies found factors related to marital or family status, psychological or social reasons for drinking, and factors variously related to control, dependency, and continuous versus periodic drinking. Two of the three studies found factors related to employment, physical health or symptoms, and motivation for help or treatment. Factors unique to the present study include trouble with the law, drug abuse, age, tolerance, family drunkenness, and parental attitudes, none of which is surprising.

Various studies have looked for typologies within the alcoholic nomenclature on the basis of Minnesota Multiphasic Personality Inventory scores (18), 16-PF scores (7), sex differences (6, 19), and character types (20). The Q-factor subtypes presented here are based only on reported behavior elicited by an alcoholism questionnaire. The discriminating variables reported here appear to contrast alcoholics with poor and good prognoses, as well as to identify a third group that emphasizes sex differences. These discriminators have been noted by others (19–22).

We currently plan to modify our Alcohol History Form in order to describe more succinctly and focus more clearly on those items and item clusters that appear to be most discriminating. We are encouraged by the fact that many of them have been shown to be relevant to treatment outcome (21–24), and we plan to explore their usefulness in treatment-outcome studies of alcoholic inpatients within the Missouri Division of Mental Health.

DISCUSSION

EUGENE M. CAFFEY, JR., M.D. (Bowie, Md.)—This substantial piece of work by Dr. Evenson and colleagues contains much material of interest to me and others who work for the Veterans Administration. It is estimated that of the nine million alcoholics in the United States, 3.1 million are veterans. In the last fiscal year (1971), we treated in our hospitals 105,000 veterans with primary or secondary diagnoses of alcoholism. From day to day an average of 1,230 veterans are treated in our specialized alcohol treatment units. We need help. How might this compilation of experience in Missouri assist us?

The authors' overall approach of examining alcoholics' responses by means of factor analysis is used often, as their references show. However, the large number of subjects and the inclusion of women are unusual, as is the enormous number of variables they chose for analysis. This kind of search for a typology and the possibility that we can, by computer, assign patients to the right treatment program are extensions beyond the commonplace.

Associates more expert in statistics confirm my impression that the design and management of the analysis were appropriate as well as comprehensive. Perhaps more factors were preserved for rotation than were necessary; and perhaps the among-type differences revealed by the discriminant analysis were artificially enlarged by analyzing groups previously defined on the basis of within-group similarity and among-group differences. However, the results were not altered by these esoteric considerations. With all my exogenous confidence, though, I wonder at the empirical basis for the statement, "It should be noted, however, that this hit rate [90 percent correct assignment to one of the three types] would probably decrease on cross-validation."

When we return to the array of other studies with which this one is compared, our pool of information loses its statistical

TABLE 3
*Discriminant Function Classification of Three Q-Factor Groups of Alcoholics**

Q-Factor Classification	Discriminant Function Classification			
	Group 1	Group 2	Group 3	Total
Group 1	67	6	0	73
Group 2	5	53	2	60
Group 3	0	1	12	13
Total	72	60	14	146

* Hit rate=90 percent.

tively related to drinking on the streets and negatively related to drinking at home.

Factor 15 essentially reflects a negative attitude toward Alcoholics Anonymous as a treatment modality.

The transposed or Q-factor analysis resulted in seven patient clusters. The first three clusters accounted for 144 of the 146 subjects. The remaining two subjects could be classified by substantial loadings (0.58–0.59) on one of the first three clusters, and they were so assigned. The remaining factor loadings on all three clusters ranged from 0.62 to 0.99, and the discriminant function analysis was made on the basis of these three groups. The three groups or clusters consisted of 73, 60, and 13 subjects, respectively. The results of the discriminant function analysis are shown in tables 2 and 3.

Table 2 shows the first 23 items that entered the discriminant function, ranked in descending order according to their unique contribution to discrimination across the three groups, along with the group means for each item. High means among the three groups are asterisked. It can be seen that group 1 is characterized primarily by younger, married, and employed subjects. Members of group 1 are more likely to be living with their primary family group. In contrast, members of group 2 are more likely to be older, unemployed, and living alone or with friends. In addition, members of group 2 show signs of greater deterioration, such as blackouts, benders, and nightmares. Members of group 2 also tend to drink more continuously and to show more invalid responses to the questionnaire. Group 3 appears to consist primarily of female alcoholics. In addition to the sex difference, members of group 3 tend to live with their spouse or a relative and to drink at a friend's home. Members of group 3 also tend to blame their spouse for their drinking and to be positively motivated for clinic treatment, but negatively motivated toward Alcoholics Anonymous.

The Linear Discriminant Function (LDF) program used in the data analysis is a stepwise program. As a result, the program initially examined the relationship between 80 variables and membership in the three Q-factor groups and found that the variable "unemployed" was the best discriminator across groups. The program then looked at the relationship between the remaining 79 variables and group membership, but with "unemployed" used as a covariate (statistically controlled). In other words, in the subsequent steps it was as if all patients had the same employment status. At the second step the variable "age" entered the LDF. After the second step, it was as if all patients were the same age (as well as having the same employment status). Thus each subsequent variable entering the LDF contributed a unique source of variance. In short, younger age alone did not account for the social-historical differences between groups 1 and 2, nor did sex alone account for the differences in group 3. The variables shown in table 2 were the first 23 variables entered by the LDF program, and the remaining variables contributed little to group discrimination.

Table 3 shows the efficiency of the derived discriminant function in assigning membership to one of the three groups. The achieved hit rate of 90 percent suggests that it is feasible to assign newly admitted alcoholics to one of three groups, based on their responses to the Alcohol History Form. It should be noted, however, that this hit rate would probably decrease on cross-validation. It seems reasonable to hypothesize that, for instance, membership in group 2 would be related to subsequent poor outcome or adjustment. If, in our continuing studies, this proves to be true, then the LDF formula can be used as a prognostic indicator and special programs can be developed to treat this group.

DISCUSSION

It is particularly interesting to compare the results of this factor analysis with similar studies recently reported. In particular, we would contrast our results with the study of alcoholic inpatients at Fort Logan, Colo. (4). The Fort Logan study is unique in that the item factors themselves seem to form a typology. That is, the first three factors are roughly related to "broad-severity hard-liquor drinkers," "social beer drinkers," and "deteriorated wine drinkers," respectively. In contrast, we find all three types of alcohol intake related to a single factor, "total ethyl alcohol intake." In addition, none of the three types of alcohol intake in our study differentiates across the three patient clusters or types as identified by Q-factor analysis. Another factor-analytic study by Hoffmann and associates (5) found no specific factors for either alcohol intake or type of beverage. It should be noted that these factor studies had patient populations similar to our own.

A factor-analytic study of psychiatric symptoms by Miller and associates (16) concluded that alcoholics are substantially more labile in their manifestations of psychiatric symptoms at time points before, during, and after treatment as compared with patients with other psychiatric diagnostic classifications. Other investigators (17) have noted that the alcoholic has vastly different subjective feelings depending on whether he was tested during withdrawal or not. Thus the timing of data collection in alcoholism studies may result in different factor structures. It is also possible that persons designated as alcoholic form a homogeneous group only by virtue of a single symptom: drinking to excess. Other factors (symp-

holism. Such types would, presumably, cut across symptomatic drinking patterns.

Finally, the groups found by Q-factor analysis were analyzed by means of a stepwise linear discriminant program (15) in order to determine which items from the Alcohol History Form contributed a unique source of variance in discriminating across groups. Eighty of the 118 variables were selected for discriminant analysis, and care was taken to ensure that the 80 items reflected the major independent sources of variance in the original factor analysis.

RESULTS

The results of the factor analysis are shown in table 1. Two separate Varimax rotations were employed. The first rotation included 12 factors with Eigen values (relative proportion of variance) greater than 2. The second rotation included 19 factors with Eigen values greater than 1. Our primary consideration was to note whether rotating fewer factors would significantly alter the factor structure. The first 12 factors for both rotations were essentially identical. Table 1 shows 15 factors, since the remaining factors tended to replicate earlier factors or to represent trivial and artifactual content. Factor loadings and frequency of endorsement are also shown.

Factor 1 is a cluster of items representing psychological reasons for drinking. Although loneliness is the most frequently endorsed item, items referring to feelings of sadness, anger, and self-pity load the most strongly on this factor.

Factor 2 relates to use of other drugs, particularly as a substitute for alcohol. Amphetamines, opiates, and mind expanders are the most frequently noted, in that order.

Factor 3 relates primarily to marital status and can probably be best described as living with spouse and dependents, as opposed to being single and living alone.

Factor 4 relates to loss of control over drinking behavior and advanced symptoms such as benders, blackouts, and morning drinking.

Factor 5 is primarily related to the age of the patient and is therefore also related to the number of years of drinking and age when the patient was first hospitalized for drinking.

Factor 6 reflects total amount of alcohol intake and includes loadings for intake of beer, wine, and hard liquor. The highest loading is on a derived score reflecting total intake of ethyl alcohol. This factor is of particular interest, since it includes all forms of alcohol as opposed to reflecting differing patterns for beer, wine, and liquor drinkers.

Factor 7 is a cluster of items indicating that the patient's parents were not permissive regarding the use of alcoholic spirits and that the relationship between patient and parents was not a close one.

Factor 8 consists of items indicating that the patient's biological relatives or immediate family members are likely to be alcoholic or have problems with alcohol.

TABLE 2

Discriminant Function Analysis for Three Groups of Alcoholics

Item	Univariate F Value	Group 1 Mean	Group 2 Mean	Group 3 Mean
1. Unemployed	16.07	0.27	0.72*	0.62
2. Age	5.60	43.32	48.70*	44.54
3. Has blackouts	4.83	0.77	0.88*	0.54
4. Lives with relatives	4.54	0.22	0.27	0.62*
5. Sought help from spouse	3.92	0.29	0.12	0.31*
6. Sex	3.34	1.07	1.17	1.39*
7. Drinks at friend's home	3.12	0.04	0.03	0.15*
8. Lives with friends	2.55	0.03	0.10*	0.00
9. Sought help from physician	2.41	0.32*	0.27	0.15
10. Has withdrawal symptoms (nightmares)	3.04	0.11	0.18*	0.15
11. Holds spouse responsible	1.82	0.07	0.07	0.15*
12. Goes on benders	1.76	0.94	0.95*	0.77
13. Home problems precipitated drinking	1.87	0.25*	0.18	0.15
14. First started drinking socially	2.31	0.15	0.18*	0.00
15. Spouse has negative attitude	2.32	1.97*	1.38	1.54
16. Nervousness precipitated drinking	1.80	0.60	0.70*	0.62
17. Has negative attitude toward Alcoholics Anonymous	1.86	0.92	1.08	1.23*
18. Frequency of meals	1.74	7.34*	6.23	6.77
19. Biological relative is an alcoholic	1.67	0.99*	0.60	0.85
20. Sought help from minister	1.60	0.30*	0.18	0.23
21. Sought help from clinic	2.25	0.45	0.53	0.54*
22. Frequency of drinking	1.97	2.11	2.92*	2.77
23. Number of invalid responses	4.60	0.43	1.27*	0.23

* The highest mean value for the three groups on this item.

Factor 9 reflects frequency of drinking (drinking throughout the day as opposed to drinking periodically or during evenings and weekends) and deterioration (number of invalid responses).

Factor 10 contrasts the employed alcoholic (who has problems with his supervisor and who misses work) with the patient who has no job.

Factor 11 contrasts the alcoholic who sees himself as responsible for his problem with those who put the blame on others, especially spouse or friends.

Factor 12 relates to those alcoholic patients who have sought and accepted help in the past. Main sources of help include physicians, ministers, clinics, relatives, friends, spouses, Alcoholics Anonymous, and previous hospitalization.

Factor 13 consists of items suggesting that the alcoholic feels his tolerance is decreasing and reports fearfulness accompanying withdrawal.

Factor 14 relates to trouble with the law. It is posi-

TABLE 1
Results of Varimax Factor Analysis of 118 Alcoholism Questionnaire Items

Factor	Eigen Value	Factor Loading	Frequency
Factor 1: Psychological precipitants	7.47		
Sadness		0.69	224

Factors in the Description and Grouping of Alcoholics

BY RICHARD C. EVENSON, PH.D., HAROLD ALTMAN, M.D., M.P.H.,
IVAN W. SLETTEN, M.D., AND RAYMOND R. KNOWLES, M.B.B.S., D.P.M.

Data collected from 1,023 alcoholic inpatients by means of a self-rating instrument were used to explore the dimensions and subgroupings of alcoholism. Fifteen factors derived from a factor analysis reflected the variety of psychological and social dimensions of the problem. Three subtypes of alcoholism emerged from an inverted (Q) factor analysis. These subtypes were characterized by means of a linear discriminant function analysis. Two subtypes appeared to be related primarily to severity, and the third primarily to sex and marital variables.

THERE HAS BEEN a continuing interest in the development of alcohol behavior-history questionnaires designed to gather information from those patients designated as alcoholics. These instruments typically include items concerning patterns of drinking behavior, history, symptomatology, and attitudes (1–3). Factor analyses of such scales suggest that they are multidimensional, although the factor structures are not uniformly replicated (4, 5). There has also been considerable interest in identifying typologies (6, 7) and phases of alcoholism (8) with a population of alcoholic patients. The word "alcoholic" apparently does not pertain to a unitary set of symptoms, much less to a particular kind of etiology. Yet the need for careful description of the dimensions along which people classified as alcoholics can be seen to differ has important implications both for prognosis and for treatment-outcome studies.

As part of a statewide computerized information system called the Standard System of Psychiatry (SSOP), standardized information has been routinely collected from inpatient alcoholics within the Missouri Division of Mental Health for several years. Information is collected on a checklist form and transmitted by means of leased lines to a computer center at the Missouri Institute of Psychiatry in St. Louis, where it is processed and stored and a computer report is printed out at the originating terminal. Details of the SSOP system have been presented elsewhere (9). Data for analysis are available on request from the central computer files and include information collected specifically on alcoholism by means of an instrument called the Alcohol History Form.

The purpose of this study is to analyze and describe those dimensions and subgroupings found in an inpatient population of alcoholics within the Missouri Division of Mental Health, based on information routinely collected by means of the Alcohol History Form.

METHOD

Data for the study were gathered from alcoholic treatment centers at eight facilities throughout the Missouri Division of Mental Health between August 1968 and September 1969. During this period of time patients admitted to inpatient services at the alcoholic treatment centers routinely completed a two-part Alcohol History Form (10) consisting of 76 items that generated 157 variables. Patients completed the checklist questionnaire themselves, with instructions and guidance from the staff. A total of 1,395 inpatients completed at least one part of the questionnaire. Of these, 1,023 adequately completed the entire instrument; these protocols were the basis for the present analysis. The mean age of the sample was 45.6 years (about 84 percent were between 30 and 59), and 13.7 percent of the sample were women. About 22 percent of the sample were also involved in some form of drug abuse, although only six to eight percent used dangerous drugs or narcotics to any significant extent.

Of the 157 variables, we chose 118 for factor analysis, taking particular care to eliminate redundant and artifactually related items. Following item intercorrelation, principal components analysis and Varimax rotation to simple structure were employed (11). The aim of the factor analysis was to clarify symptom and attitude patterns as reflected by the questionnaire.

Subsequently, a subsample of every seventh patient (N = 146) was employed to generate a transposed correlation matrix, which was similarly factor analyzed. Such a transposed or Q-factor analysis (12) has typically been employed to explore the domain of patient clusters or typologies (13, 14). The present aim of the Q-factor analysis was to investigate subgroupings of alcoholics that could conceivably represent typologies or phases of alco-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972. The original title of this paper was "Alcoholism: Symptom or Syndrome?"

The first three authors are with the Missouri Institute of Psychiatry, University of Missouri School of Medicine, 5400 Arsenal St., St. Louis, Mo. 63139, where Dr. Evenson is Research Associate, Dr. Altman is Clinical Assistant Professor, and Dr. Sletten is Professor. Dr. Knowles was formerly Associate Director, Division of Mental Health, Missouri Institute of Psychiatry.

charged as improved with a diagnosis of psychophysiologic skin reaction and psychoneurotic depression. AMHTS had suggested nonadmission.

Among the eight other service misclassifications for which records were available and in which the patient was treated by surgery or medicine although AMHTS had suggested psychiatry, there were four cases in which the discriminant function analysis of AMHTS test results was correct. One patient was admitted to medicine for evaluation of low back pain. The final diagnosis was conversion reaction, and the patient was referred to psychiatry, as suggested by AMHTS. Another patient was admitted to medicine for evaluation of gastric ulcer. The final diagnosis was psychophysiological gastrointestinal disorder, leading to a referral to psychiatry, as suggested by AMHTS. A third patient appeared in the admitting office complaining of tenseness, nervousness, and inability to sleep. He wanted an opportunity to talk to a doctor. This was provided by a physician on the medicine service, who decided that the problems were not serious enough for referral to psychiatry or for admission. AMHTS had suggested referral to psychiatry. The fourth patient was worked up by surgery in the admitting office; there was no record of any surgical findings. This patient had a long history of psychiatric problems and has a service-connected disability for anxiety neurosis. AMHTS suggested referral to the psychiatry service.

In the remaining four cases there was no indication in the hospital record that another service should have been involved.

In summary, of seven disagreements between AMHTS and the admitting physician's decision to assign to the psychiatry service, the classification suggested by AMHTS had some validity in three cases. Of the eight disagreements where the patients were assigned to medicine or surgery although AMHTS had suggested psychiatry, the AMHTS classifications were found to be correct in four cases. Altogether, among the 15 disagreements, AMHTS turned out to be essentially correct in its assignment of seven cases.

DISCUSSION

With the increasing number of patients being referred for care to the VA hospital system, improved techniques for working them up efficiently and assigning them to proper treatment programs are needed. The results of this study suggest that AMHTS can be an aid to the admitting physician, expecially with respect to psychiatric patients. The present AMHTS system provides a fairly good simulation of the physician's decision in the admitting office.

The findings of this study also indicate that classification as to which service should care for the patient, and whether he should be admitted to the hospital, remains ultimately a medical decision. In addition to assisting the physician by suggesting how to assign the patient, AMHTS provides a history and the results of a battery of physiologic, psychological, and chemical tests. These speed up and simplify many of the routine aspects of a patient's admission work-up.

These findings point toward ways in which the AMHTS system can be improved. The VA admitting office decision may be based on information that is not available to AMHTS at present. For example, the questionnaire does not take into account the patient's chief complaint or presenting problem. We are altering the questionnaire to make it more comprehensive and better related to the purpose of the patient's hospital visit.

On the other hand, the AMHTS system provides information that has not formerly been used by the VA in the decision-making process. An example of this is that three nonadmitted patients were recalled to the hospital and admitted on the basis of the following findings: two had EKG abnormalities and one had an abnormal chest X ray.

The results with the psychiatric questionnaire scales suggest techniques of approaching medicine and surgery. We have recently been analyzing the questionnaire material for the triage and admission/nonadmission processes primarily by body system—heart symptoms, eye symptoms, etc.—except in the case of psychiatry, where we have utilized three previously validated psychiatric instruments.

We are now recombining all the questionnaire items on the basis of judgments by experienced physicians as to whether the items are primarily medical, surgical, or psychiatric in nature. The reorganized data will be subjected to new multivariate analyses to determine whether the modified questionnaires produce improved factors and discriminations with medical and surgical patients (as well as with psychiatric ones) for use in triage and admission/nonadmission decisions.

Do your hands sweat or tremble enough to bother you?
Do you smoke?

The Holmes and Rahe Scale

The Holmes and Rahe Scale (3) provides a quantifiable measure of ongoing social stress. It includes 41 items; following are some examples: death of a spouse, divorce, jail term, personal injury or illness, retirement, sex difficulties, business adjustment, change in financial state, mortgage of more than $10,000, son or daughter leaving home, outstanding personal achievement, and wife beginning or stopping work.

Selective Service Questionnaire

Finally, a set of psychiatric questions was derived from the Selective Service questionnaire; this provides information about personal and familial psychiatric history and thus offers another dimension in assessing the patient's psychiatric condition. Here are the questions:

Do you smoke now?

Have any of your blood relatives suffered from the following: alcoholism or drug problems, nervous or emotional problems, or suicide attempts?

Have you had any of the following: nervous or emotional problems, alcoholism or drug problems, suicidal thoughts or attempts, or epilepsy?

METHOD

The present report contains findings on psychiatric patients seen in the admitting office on whom a decision had been made whether or not to admit for inpatient care. In particular, we are looking at whether AMHTS can simulate the physician's decisions in the admitting office. A preliminary study providing test-by-test analysis of data from these investigations has been presented previously (6).

Veterans were tested by AMHTS while they were undergoing the admitting process at the Gainesville Veterans Administration hospital. Testing was voluntary; 241 of the 818 patients contacted agreed to be screened. Fifty-two of these patients were referred to the psychiatry service for evaluation. Subsequently, 28 patients were admitted and 24 patients were not admitted to the hospital. (During the study 30 percent of all veteran applicants who appeared at the admitting office were not admitted.) The admitting physicians did not receive any information about the patient's test results until after they had completed the admission procedure and decided whether or not to admit the patient. There were no significant racial or age differences between the admitted and not-admitted psychiatric patients.

In the Veterans Administration hospital admission procedure there are two main decisions: first, which service—medicine and its specialties, surgery and its specialties, or psychiatry—should work up the patient, and second, whether the patient requires admission to the hospital. The present research looks at both of these. The research subjects are therefore divided into three main categories and the two classes of admission/nonadmission.

Stepwise discriminant function analyses were performed by hospital service with respect to the referral to service and admission/nonadmission decisions. A factor analysis was performed from the AMHTS questionnaire data. Factor scores were computed for each patient and then submitted to discriminant function analysis.

This report focuses on results for psychiatric patients; further work is being done on medical and surgical patients and the results will be reported later.

Our final task in this study was to examine the hospital records and AMHTS printouts on all participating psychiatric patients with respect to the two admitting procedure decisions and the analysis by discriminant function. From this examination we sought to determine the reasons for the failure in agreement between the multivariate analyses and admitting physician's decisions.

RESULTS

A discriminant function analysis was done using all AMHTS questionnaire items and physiological and chemical tests. In the triage decision, the total psychiatric scale was the only discriminating item; it successfully simulated the assignment of patients to the psychiatric service. When the factor scores in the 20 questionnaire indices were used in the triage discriminant function, the psychiatric factor was highly significant ($F = 26.2$). Of the 52 patients treated by the psychiatric service there were seven disagreements between the admitting physician's decision and the AMHTS classification with respect to the service triage and admission/nonadmission. Hospital and AMHTS records for all these patients were available for study. Six of the disagreements involved the service and one the admission decision. In addition to these seven, there were nine patients treated by medical and surgical services whom AMHTS had assigned to psychiatry. The records of all but one of these patients were available for review.

Among the six patients treated by psychiatry who were assigned to another service by the entire AMHTS system there were two cases in which AMHTS was not in error. One patient was admitted to psychiatry for workup of chronic diarrhea following peptic ulcer surgery in 1964. AMHTS suggested referral to the surgery service. This patient obviously bordered on two services.

The other patient in psychiatry complained of headaches. Four months earlier this patient had been operated on for a malignant tumor of the bladder, and he was still receiving follow-up treatment for this problem. AMHTS suggested referral to the surgery service. He too was obviously a borderline case. In the other four cases there is no indication in the hospital record that another service should have been involved.

The one psychiatric patient who was misclassified according to the admission decision was admitted for evaluation of a number of somatic complaints: backache, headaches, muscle spasms, and dermatitis. He was dis-

Psychiatric Screening with Automated Multiphasic Health Testing in the VA Admission Procedure

BY RICHARD E. GORDON, M.D., PH.D., LESLIE BIELEN, M.ED., AND ANNE WATTS

A total of 241 veterans who applied for admission to a Veterans Administration hospital underwent automated multiphasic health testing and services (AMHTS). The authors compare test findings with the admitting physician's decision as to whether or not a patient should be worked up by the psychiatry service for admission. The findings indicate that an AMHTS system may be able to assist the admitting physician in making this decision: Discriminant function analysis from the patient's history questionnaire simulated the physician's decision fairly well.

ONE USE OF AUTOMATED multiphasic health testing and services (AMHTS) that offers great promise for the efficient delivery of health care is in the selection and triage of patients for psychiatric and other types of psychological, medical, and surgical services (1, 2). AMHTS provides the physician with an inexpensive but highly accurate overview of the status of his patient's physiological, biochemical, and psychological systems. It also provides a summary of family and personal medical history, highlights current symptomatology, and can offer the physician a health risk evaluation for each of his patients.

In researches at the University of Florida College of Medicine and the Gainesville Veterans Administration hospital, we are assessing the value of psychosocial tests and instruments in an AMHTS system for separating normal persons from those with medical and psychosocial difficulties, and for assigning those with emotional problems to appropriate medical social care. As part of the project we have been investigating applicants in the hospital admitting office and attempting to discover ways in which AMHTS can assist this process.

The standard tests and procedures we are utilizing in the AMHTS center are the following: 1) general history, containing a personal and family medical history, basic demographic data, and a systemic symptom review; 2) glucose challenge test; 3) chest X ray; 4) anthropometry; 5) urinalysis; 6) electrocardiograms and vector cardiograms; 7) blood pressure; 8) cervical Pap smear, as appropriate; 9) audiometry; 10) spirometry; 11) visual acuity, phoria, depth perception, and color vision; 12) tonometry and visual fields; 13) blood chemical profile; and 14) hematology.

The authors are with the Department of Psychiatry, University of Florida College of Medicine, Gainesville, Fla. 32601, where Dr. Gordon is Associate Professor and Ms. Bielen and Ms. Watts are Research Assistants. Dr. Gordon is also Research Director, Automated Multiphasic Health Testing Center, University of Florida College of Medicine. Ms. Watts holds a Diploma in Applied Social Sciences, which is the British equivalent of a Master's Degree in Social Work.

This study was supported in part by Regional Medical Program grant PHS-RM-0024-92C and by grant 01/3210.1/69.01 from the Veterans Administration.

The authors would like to thank Drs. John Thornby and Carolyn J. Hursch for their assistance.

PSYCHIATRIC TESTS

In addition to these tests and procedures, we are also examining the utility of a battery of psychiatric screening instruments that draws heavily upon previous work by Holmes and Rahe (3), Leighton and associates (4), and members of the department of psychiatry at the University of Florida College of Medicine (5).

The results of all the psychiatric tests are being examined independently as well as together in a single psychiatric scale.

Modified Leighton Scale

The first list of questions under study was taken largely from the Leighton test (4). It deals primarily with psychiatric symptoms and was pretested at the University of Florida on a local population (5). The questions follow:

Do you have any physical or health problems at present?
Have you ever used any medicine or tranquilizers for your nerves or to help you sleep?
Do you feel in good spirits?
Are you bothered by your heart beating hard?
Are you bothered by nervousness?
Are you bothered by nightmares?
Do you have trouble getting to sleep or staying asleep?
Do you feel tired in the morning?
Do you tend to lose weight when worrying?
Are you bothered by cold sweats?
Have you ever felt you were going to have a nervous breakdown?
Have there been times when you felt low or hopeless?
Do you have spells of dizziness or fainting?
Do you have frequent headaches?

Kubie [3]) is that the most effective and powerful way to learn about human suffering is to listen to a person and to struggle with him in discovering and resolving his needs and difficulties. To omit, shortchange, or compromise this aspect of any mental health trainee's growth invites the deterioration of our capacity to respond therapeutically in any context.

THE NONACTIVIST POSTURE

Parallel stresses are placed on trainees who maintain a major commitment to a relatively less active posture in their work. A tendency toward extravagant self-criticism seems to occur frequently. In the context of others who seem so certain of their purpose, this attitude may be felt as weakness and indecisiveness and may be threatening to the trainee's forming sense of direction and purposiveness. Beyond this, the trainee may feel that such doubts represent his failure to be in tune with the times and to hold fast to worthwhile goals when others appear to be pursuing them with vigor and determination. Issues of morality and politics, of injustice and misplaced investment come to predominate. In the extreme, one's sense of himself and his basic worth becomes shrouded with guilt and an uneasy feeling that he is trying to learn something both right and wrong—a good thing, perhaps, but not the right good thing or not enough of it. Following is a poignant example of the type of dilemma that these trainees may face: A black patient who is deeply committed to therapy tells his white therapist that their next session coincides with a street-sweeping drive in his ghetto neighborhood and that if they are to meet, the therapist will have to join him. To say "no" to such a request augments the young therapist's questions about the depth of his social values, as well as the genuineness of his commitment to therapy, for apparently both could be served only by joining his patient in the street.

An attitude of defensiveness, never the companion of clear thinking, often arises with these trainees' being left in an obsessional morass from which the only escape seems to be a more totalistic self-definition through painfully ambivalent surrender in one direction or the other. Even if the trainee does not surrender, an electrified atmosphere attributes undue significance to anything he does or says. Participation in a certain conference is read as a sign of a trainee's switching camps and allegiances. A trainee who, due to incidental circumstances, temporarily interrupts his analytic training is openly hailed by many of his colleagues for having finally seen the "light." One can imagine the sense of strain and confusion the hero of such celebrations undergoes.

When, as a part of this process, a rigid commitment is made to more reflective therapeutic modes, the content of allegiances may differ but not the quality of a totalistic definition. A caricatured psychoanalytic posture is adopted (2). Reflection is replaced by resolute detachment, relative inactivity by unresponsiveness, and empathy by impersonal "understanding." The trainee, in short, becomes inhuman and tends to regard his patients in a similar light. Currently, while some trainees are inclined toward or defensively assume such a posture, the fact that the social and professional pressures to be this way are less insistent (in contrast to the activist position) probably accounts for the relative infrequency of this type of rigid professional definition. More often, in such trainees, a sense of professional isolation mirrors a sense of personal isolation and of being cut off from the main stream. Honest self-scrutiny and doubt cannot be openly voiced without the risk of yielding to pressure to change one's position or else of publicly discrediting one's self-worth and therapeutic stance. Yet our contention is that although some trainees may pay a price for being out-of-date, still higher dues are paid by those trainees who commit themselves to being fashionable activists.

CHOOSING SIDES

Each of these positions, when polarized, is weakened and rendered the less by rigidly excluding the other. While the situation might have been reversed in the past, it seems to us that now the activist position tends to be defined primarily in opposition to and in defense against the less active position. Striking splits also occur within the teaching staff and leave trainees with few, if any, role models for the successful integration of both points of view. In fact, staff splits tend to offer social and group support for "taking sides." A sense of the complementary roles of individually oriented psychotherapy and broader-scale community intervention seems to be lacking. Instead they are seen as competing, often in a very real sense given limited training funds and trainees' limited time for performing service.

To illustrate, a group of trainees initiated a seminar in radical psychiatry to coincide in time with a more traditional therapy seminar. All trainees were thus forced to make an unambiguous choice between the two. Within such a context, the trainee is limited in his freedom to evaluate critically and fairly his own and alternative postures. Peaceful coexistence, even when maintained by many trainees, covers a highly inflammatory situation in which few opportunities are lost (often by staff) for vehemently defending one stance while covertly or overtly disparaging the other. Interventionists are seen as deluded saviors with chips on their shoulders, while reflectively oriented psychotherapists are seen as reactionary bigots. Trainees are stuck with the disastrous alternative of having to choose sides or to resolve issues on their own. The learning and personal growth essential to the development of a therapist of whatever inclination cannot occur where internal and external pressures toward preemptive ideological commitment to one mode or the other exist in raw form.

Our bias as professionals committed to a reflective therapeutic modality cannot help but influence our perceptions of current training issues and our thoughts about what to do. Still, two observations seem relatively independent of our particular bias. When trainees, by virtue of a confluence of their own needs and certain professional pressures, are placed in the position of "buying" an ideological or theoretical point of view, learning and growth suffer. Imaginativeness and the exploration, as well as the acquisition, of skills can be severely obstructed in a value-saturated, heavily politicized atmosphere. Sharing therapeutic experience as a way of teaching and learning can flourish only when such pressures are removed and nonjudgmental acceptance prevails instead. Our second observation (elaborated by

abandon psychotherapy as a relevant activity and to pursue the narcissistic goal in some other clinical area.

This type of resolution is of interest to us since it seems to be closely tied in with the current trends in mental health thinking we have described. Considerable stress is placed upon the trainee therapist by the readily available alternative of joining the ranks of community activists—a stress felt all the more keenly because such activities are fashionable and represent the implementation of ideas whose time is long overdue. Part of the motivation for joining ranks may lie in the (fantasied) hope of realizing within this realm the frustrated wish to be curative and an (infallible) agent of change. Rather than accepting the limiting implications of one's experience, one turns, with redoubled hopes and wishes, to new fields of endeavor where he hopes to ultimately reach the narcissistic goal.

THE ACTIVIST POSTURE

The danger here has been best expressed by Erikson's (7) notion of "wholeness" and "totality" in identity formation. Wholeness is flexible, permeable, and naturally integrated; totality, on the other hand, involves a rigid definition of self and others, a delineation of the self by uncritically embracing some ideas and identity patterns and sharply excluding others. Erikson further pointed out that totalistic identity patterns are most likely to emerge in periods of social uprootedness or, to extend this idea, in periods of rapid and discontinuous social change. When the social ground upon which one stands is shifting and lurching, one must turn inward and create, often artificially, stable boundaries and self-definitions. A disdainful attitude toward old techniques, values, and experience, although perhaps having a certain innovative value, may lock one into a way of thinking such that he uncritically disregards anything that smacks of the old and uncritically champions whatever might be new.

In this context trainees who become committed to community activity as a mode of intervention may form a more totalistic style of identity, which is best summarized by Eldridge Cleaver's remark (often referred to by community interventionists), "If you're not part of the solution, you're part of the problem." A brief catalog of what tends to be included within the boundaries of the activist approach might be: 1) a premium placed on active intervention and a belief in the efficacy of action; 2) concern for the social causes of patients' distress; 3) a highly partisan, perhaps romantic, empathy for the patient as victim (8); 4) emphasis on the politics, as opposed to the psychodynamics, of therapeutic intervention (9); and 5) disdain of hierarchies, status, and differential skills of professionals. For example, one trainee's therapeutic work with a black patient went seriously awry because the therapist was more interested in the patient's experience as a black man than his obvious depressive difficulties. In numerous instances we have seen trainees view and respond to minority group membership as the core psychological problem, the patient's declarations to the contrary notwithstanding. Active intervention (doing something "real" to or for the patient) is seen as maximally suited to deal with such problems and is elevated from the status of an expedient therapeutic mode to an overriding principle. A regard for finer, more subtle psychodynamic issues is dismissed as fanciful and unrealistic.

In addition, there is a cogwheeling of the styles of trainees who adopt this approach and of the style of operations (if one can describe it as such) inherent in this widely shared point of view. The failure of one plan of action seems to be regarded as a limitation in the breadth and scope of the intervention and as cause for more elaborate plans: If a certain amount of activity seems ineffective, double that amount should be more effective. To provide theory and logic to this approach, psychiatric illness in itself is denied and replaced by notions of social ills. Once these are righted, patienthood will somehow disappear. A social gathering in which patients meet staff members on equal grounds and often manage to outdo them in various activities is regarded as absolutely valid proof for this ideological theory. Questioning the basic assumptions or doubting the essential "rightness" of the ideology of active intervention tends to be heard as tantamount to heresy. An apparent air of idealism, warmth, cooperation, and mutual support makes the ranks of the community people so much more attractive than the isolation, authoritarian inequality, and the resultant sense of impotence one imagines finding among the traditional professionals.

Feelings are to be shared, not to be used as data, and the resultant gratification from mutual give and take is justified by egalitarian principles rather than by therapeutic efficacy. While imbued with such fervor, younger professionals rarely adopt the point of view held by an older expert who thinks of his long-standing professional interventions in community affairs primarily as lessons in humility. Challenges from within the ranks rarely arise, and those from without may be brushed aside as coming from the unenlightened. Instant expertise by virtue of declaring one's convictions is possible because essentially no one knows more than anyone else about the task of expanding mental health services beyond their traditional boundaries. In other words, considerable external support exists for assuming a stance that is, in part, a defensive effort by the trainee to quell doubts about his therapeutic efficacy through a commitment to action.

While this configuration does not describe any given individual, we contend that it does reflect a totalistic identity pattern toward which some mental health trainees are both pushed and inclined. Such a definition of one's professional position clearly has detrimental effects. By replacing the learning process with one of ideological commitment, the trainee forecloses on his options to reexamine and readjust what he is doing. More importantly, we fear, it invites the disillusionment, scorn, and fury of those nonprofessionals and clients who trust the professional's implicit promise to be the agent of change.

This quotation provides some indication of the massive change in perspective that is often required of the progressive mental health worker. It is as if the muted social and political backdrop against which one engages in psychotherapy were suddenly and dramatically highlighted, challenging him to completely rethink his assumptions about the context he operates within. The atmosphere in which this shift occurs, however, often makes it a stultifying experience. Intense social and professional pressures create a climate, not of open discussion and rapprochement, but rather of confrontation, of missionaries struggling to enlighten primitives. In our experience it happens not infrequently that one's questions and doubts about interventionist tactics and ideological assumptions are treated not as a difference of opinion but instead as ignorance, bigotry, and social atavism. While such an attitude may characterize only the more radical proponents of community activity, it pervades the entire atmosphere within which one teaches and trains, and therefore trainees have no choice but to deal with it.

Within this framework two apparently mutually exclusive alternatives are left open to trainees: being a "good" human being (progressive, concerned, involved in remedying social injustices, and providing the most service to the greatest number of clients) or being a "good" psychotherapist (impartial, reflective, inactive, and spending a relatively great amount of time with a limited number of patients). The dilemma is undoubtedly aggravated by the fashionable quality of the first alternative and the outdated quality of the second. In short, it becomes nearly impossible to maintain the view that what one does professionally need not directly reflect one's social values or commitment to them. A sense of professional worthwhileness, then, comes to be tied more closely to a social or political point of view and to the fervor of one's adherence to that view than to actual competence and skill.

THE WISH TO "CURE"

Much has been written about the development of the professional identity of the psychotherapist, the crises that have to be overcome, and the resolutions adapted that are particular to this field (2, 3). As Kubie has described, and as anyone who has gone through the process can attest, becoming a therapist involves much more than just the accumulation of relevant information or the mastery of certain techniques. It is a living and growing experience, accomplished more by soul searching than by acquiring information. In this section we hope to describe some troublesome aspects of this growth process for the current generation of mental health trainees.

A crucial aspect of becoming a psychotherapist is the positive acceptance of one's finite and fallible means for effecting change in patients. This accounts for what Kubie (3) described as "an ill-defined sense of mourning and a weariness of the spirit" often seen in experienced psychotherapists. The freedom to see oneself as being no different than other human beings in what one tries to do for a living may be limited by the special motivation of anyone who begins training as a therapist. The fantasy that he has or should have special talents as a curative agent is a natural part of the desire to become a therapist. Whether this fantasy stems from the prospective therapist's wish to provide for others the care and grace of understanding he feels to have been denied himself—the wish, as Erikson (4) has suggested, to cure one's mother and thereby oneself or the wish to counter hostile and destructive forces in himself—the manifest wish is to effect change, to make better, to cure.

It is not surprising that this fantasy often goes beyond mere interest in acquiring professional skills and extends into political and social action. Freud's "rescue" of the banished and deviant hysteric could be seen in the same light. Understanding and accepting deviance in the guise of a medical model of treatment replaced an earlier, essentially penal one. Recently, the rediscovery of the influential power of group relationships (emerging from studies in group dynamics, milieu therapy, and sociotherapy) has rekindled and resonated with inner wishes for omnipotence and curative powers, so as to make far-reaching social and political goals seem more within reach than they really are.

The therapist's wish to cure and change invariably carries considerable narcissistic investment. To fail with a patient is seen as both a personal and professional shortcoming. The frequently expressed belief that it is not so much what one does or learns to do as a therapist but the kind of person one is (e.g., the warmth, intuition, sensitivity, and spontaneity he possesses) marks an equation between professional competence and personal worth and self-esteem.

That young psychotherapists experience their fallibility with considerable trepidation and call forth defensive protection has been clearly described by Sharaf and Levinson (5), who referred to the activation of a "compensatory defense of feeling omnipotent." While compensatory omnipotence may overstate what we are describing here, the sense of exasperation at stubborn, resistant patients that is often seen in young therapists suggests that to modify the hope of fulfilling one's wish to cure will be experienced as a deep narcissistic wound, which entails giving up a significantly regarded view of oneself. The bitter and important fact that the amount of activity the therapist engages in bears little relationship to the amount a patient changes adds insult to narcissistic injury: one cannot become a more effective therapist simply by trying harder. In fact, bearing down often produces paradoxical results, particularly with more disturbed patients.

Bibring's formulation of depression (6) is relevant here. Essentially, Bibring described depression as the perception of a disparity between narcissistically invested goals (ego-ideal) and the actual ego resources for achieving such goals. The narcissistically invested goal we have described is the wish to be curative with patients. The inevitable limitation of any therapist to accomplish this goal results in the perception of the disparity that Bibring has schematized. One way out of this dilemma is to

Current Strains for Mental Health Trainees

BY C. BROOKS BRENNEIS, PH.D., AND DORI LAUB, M.D.

Mental health trainees are currently troubled by conflicts between the "new" radical psychiatry and "old" professionalism. The conflict has been shaded with social and political overtones such that trainees view their worth as professionals not in terms of their skill, but rather in terms of how involved they are in the social and political arena. The authors feel that as a result, trainees have difficulty accepting their fallibility, tend to attribute psychiatric illness to social ills, and deal with their doubts about their therapeutic efficacy by committing themselves to action rather than to reflection.

WITH THE INCREASED emphasis on community psychiatry and community mental health—concepts that have as many definitions as potentialities—and with the more recent advent of "radical psychiatry," new problems face the developing mental health professional. We shall attempt to focus upon some of these issues as they are reflected in the inner struggle of trainees engaged in forming their professional self-images.

Whether correct or not, the term "community mental health" as used in recent years carries with it a connotation of activity. This activity has a direction implicitly derived from ideals: the rectification of current and long-standing social ills and injustices. To the extent that one becomes engaged in the struggle for social change, as leader or participant, and becomes, a priori, committed to a certain course of intervention, he loses his freedom to form a private (asocial) contract with an individual client and often secondarily redefines the situation in such a way that the treatment of an individual patient plays no significant role.

THE CURRENT CONFLICT

Yet, confusion and muddle about whether the client is an individual, an entire community, or some specific subgroup in the community, although important, is not in our opinion a major source of strain in trainees' experience. A more basic problem facing the trainee is reflected in a professional dichotomy about how to intervene regardless of how the client is defined. In community psychiatry, as reflected most sharply in the radical approach, the goal of intervention is to ensure a relatively immediate and effective response to the needs of an individual or community in distress. Individual psychotherapy strives more toward expanded awareness, understanding, and control of oneself and of his life situation. The interests and activities of the therapist, as well as those encouraged in the patient, vary accordingly. Interest in the strategies and tactics of power, especially through the organization of groups within the community, becomes central to community psychiatry. Partisanship, decisiveness, and polarization are, in this context, adaptive and therefore stand in high esteem. In contrast, reflection, delay, and a capacity for sustaining ambiguity and self-scrutiny are more adaptive and thus highly, if not exclusively, valued in individual psychiatry.

There is nothing startlingly new in this; rather, it is an updated version of a much older conflict that most generally exists between action and reflection, between the prizing of outer events and realities and inner events and realities. What is different and new on the current scene, often increasing the wear and tear on trainees to an insufferable degree and creating chasms that cannot be breached with any measure of comfort and balanced discourse, is that this venerable controversy has become strongly colored by insistent political and social values. Although arguments may have the appearance of being discussions of technical issues (that is, of the appropriate method of intervention), basically what is at stake and what makes differences of opinion so shrilly voiced are highly charged ideological attitudes and beliefs, i.e., "old" professionalism versus "new" humanism. A presumably reactionary and stratified view of society, which allows for hierarchies of different kinds, is pitted against a utopian, egalitarian, unifying one. In its extreme form an axiomatic, ideological position is taken that views traditional methods of intervention as exploitative, repressive, and essentially corrupt. To quote Goldmacher:

> The radical recognizes that psychiatry in free enterprise America has chosen to view human beings in a very narrow context, namely the intrapsychic, and to some extent interpersonal.... This way of looking at people is an explicit way of supporting an exploitative system which wants very much for people to see themselves as individuals.... By keeping people separated, the system maintains its power, and simultaneously generates feelings of powerlessness among the populace (1, p. 668).

The authors are both with Yale University School of Medicine, Department of Psychiatry, 333 Cedar St., New Haven, Conn. 06520, where Dr. Brenneis is Assistant Professor of Psychiatry (Psychology) and Dr. Laub is Assistant Professor of Psychiatry.

role in the future may largely be that of an interested bystander who receives occasional requests from colleagues in obstetrics to evaluate possible psychiatric contraindications to the performance of a therapeutic abortion. It is thus important for us to have such data available as have been reported in this study.

Even though the patients with prior histories of mild psychiatric disorders showed a trend (although not statistically significant) to experience slightly more emotional symptoms following the abortion, it is clear that the vast majority of them were satisfied with the decision that was made. Thus it appears that they did not regard their emotional state following the abortion as a significant price to pay for the benefit they obtained, and in fact 96 percent felt that their emotional health was as good as or better than before.

psychiatrist tended to recommend some follow-up psychiatric care for this group.

All respondents were asked if, under the same circumstances, they would make the same decision to seek abortion. Their replies are shown in table 2. No significant differences existed; the large majority of both groups indicated that they would undergo the same procedure again, if necessary. The fact that the psychiatric group reported more indecision may reflect its greater incidence of post-abortion symptoms or some neurotic problems about making decisions.

Patients were asked to check a list of feelings about having had the operation (table 3). The most common response was relief. While the psychiatric group was more likely to report regret, the difference between the two groups is not statistically significant.

Only 19 percent of the psychiatric group and 23 percent of the nonpsychiatric group felt that the necessity of talking with a psychiatrist was a good requirement. The rest either felt that the interview was unnecessary or expressed no opinion.

The women were asked how they would respond if a friend asked if she should have a therapeutic abortion. Only two percent and four percent, respectively, of our psychiatric and nonpsychiatric groups said that they would discourage their friend.

Pion and associates (6) have suggested that a woman's reaction to hospital personnel reflects her attitudes toward the abortion itself. They said, "Those who were not able to resolve their abortion were also dissatisfied with the services." We have scrutinized our patients' negative comments about hospital personnel in table 4. It appears that dissatisfaction was low and did not differ significantly between the two groups. Thus, if Pion and associates are correct, our psychiatric patients had no greater problems in adjusting to the abortion.

DISCUSSION AND CONCLUSIONS

If a therapeutic abortion is a significantly traumatic experience for a woman, we might expect to find evidence of a greater degree of emotional reactions in particularly vulnerable patients—those with a prior psychiatric history. Our failure to demonstrate a series of significantly different emotional reactions between the two groups suggests that women without gross current psychiatric illnesses can usually take the procedure in stride. All of the abortions were performed under legally approved hospital conditions. Even so, some public and medical attitudes that stigmatize abortion apparently made it necessary for some of our patients to avoid risking exposure by participating in our survey. Such attitudes are probably a significant cause of the guilt feelings the patients reported. It seems likely that the furtive or illegal abortions of a previous era contributed to the alleged emotional sequelae of abortions.

Our nonpsychiatric patients appear to have responded very well to the removal of the stress of their pregnancy. One similar study (7) contains follow-up data on 250 American women who received therapeutic abortions and who were essentially healthy except with regard to the stress of their current pregnancy. They, too, experienced few psychological difficulties. Our psychiatric group tended to report more emotional symptoms, but a previous study (5) showed that these symptoms were transient and significantly diminished seven months and longer following the procedure. It should also be noted that our selection process for the psychiatric group specifically chose women with a tendency to have and to report emotional symptoms.

In a recent report Ford and associates (8) discussed women with moderate to severe psychiatric problems. They said, "It would appear that the more serious the psychiatric diagnosis, the less beneficial was the abortion. Extending this reasoning, it would seem that relatively 'normal' women might benefit more from abortion. . . ." Our study confirms this conclusion. If this procedure is done on the request of the woman herself and under good legal and medical conditions, the occurrence of emotional symptoms seems to be minimal and diminishes with the passage of time even in a particularly vulnerable group of patients.

This information is particularly relevant as psychosocial indications for abortions begin to be accepted more and more. Many people anticipate that abortion on request will become more available. The psychiatrist's

had a therapeutic abortion on the recommendation of one of the four psychiatrists collaborating in this study. Each subject was asked if she would return a card giving confirmation of her present address and indicating her willingness to answer a mailed questionnaire. Nineteen of our letters did not reach the addressee and were returned. There were probably others that were also undeliverable, for we believe that some women gave a false name or address. In other instances unmarried women apparently did not wish to risk exposure and thus did not reply. Our first inquiry letter and enclosed card were so worded as to offer no clues to an unauthorized reader; however, the questionnaire that we wanted permission to send was obviously going to raise specific questions and might threaten confidentiality for some women.

A total of 157 women responded favorably by returning the card, and three others wrote asking us not to send the questionnaire. In addition to mailing 157 questionnaires, we gave 19 to women at the time of the pre-abortion interview, asking them to respond several weeks after the abortion had been performed. Of a possible total of 176, we received 126 completed questionnaires (72 percent) in time for this study.

It should be noted that a history of prior psychiatric illness was not a requirement for abortion, since the psychiatrists involved tended to evaluate the patients largely in terms of their reaction to their present pregnancy. However, of the 126 patients who responded, 52 had given a history of prior psychiatric illness at the time of the evaluation interview. None was seen as currently suffering, or having ever suffered, from a major psychiatric illness. In this group (to be called the psychiatric group) we have placed all of those with a history of an emotional disturbance at any time of life except in relation to the unwanted pregnancy. These emotional disturbances include anxiety symptoms, attacks of depression, problems with insomnia, and a variety of psychophysiologic disturbances for which medical and/or psychiatric treatment was obtained. Of course, it is to be hoped that extensive, successful prior psychotherapy would reduce an increased vulnerability to emotional stress, but none of these women gave a history of such treatment. Our contrast group, the nonpsychiatric group, contains women with no prior history suggestive of particular emotional vulnerability to stressful experiences.

By comparing these two groups we believe that any emotional impact of the therapeutic abortion will be most effectively shown, since in one group we are scrutinizing emotional effects in presumably vulnerable individuals, whereas the others are probably less vulnerable. In this paper we have selected for comparison only those questionnaire responses which specifically illustrate the emotional effects of a therapeutic abortion. A detailed report of other effects is in preparation for presentation elsewhere.

RESULTS

The study group consisted of black and white women from all socioeconomic levels. The subjects ranged in age from 15 to 41 years. The psychiatric group, with a mean age of 25.2 years, was significantly older ($p<.01$) than the nonpsychiatric group, which had a mean age of 22.5 years. Although there were more married and divorced women in the psychiatric group, the differences between the two groups in marital status were not statistically significant.

Our questionnaire probed several aspects of the post-abortion health of the respondents. All of the psychiatric group and 96 percent of the nonpsychiatric group reported that their general health was better or normal. Ninety-six percent and 92 percent, respectively, said that their emotional health was better or normal.

A checklist invited respondents to report on emotional symptoms that had occurred since the abortion; answers are shown in table 1. Here a distinct trend appears in that the psychiatric patients more frequently listed the presence of emotional symptoms. However, the prevalence rate is not high, and the only significant difference between the two groups appeared in the symptom of sleeplessness.

The occurrence of illnesses since the abortion was evaluated by a section in which the women recorded their personal histories. The incidence of illness was low, and no significant differences could be detected.

All patients were asked if they had had psychological or psychiatric care since the abortion. Twelve percent of the psychiatric group reported such treatment, as opposed to three percent of the nonpsychiatric group. It is not surprising to see a trend for more treatment in the patients with a psychiatric history since the evaluating

Therapeutic Abortion and a Prior Psychiatric History

BY JOHN A. EWING, M.D., D.P.M., AND BEATRICE A. ROUSE, M.ED.

A follow-up study of 126 women who received abortions on psychiatric grounds revealed that the 52 women with a history of prior psychiatric illness did not experience significantly more post-abortion emotional reactions than the others. Ninety-six percent of the psychiatric group and 92 percent of the others reported that their emotional health was better or normal afterward.

WHERE AND WHEN stringent laws have existed against therapeutic abortion, this procedure has usually been permitted only when the life of the mother was threatened. From the psychiatric point of view this usually meant a severe current psychiatric illness, often manifested in convincing suicidal attempts, or a prior history of severe psychiatric illness associated with pregnancy or child rearing. Some authors (1) have pointed to the fact that under such legal conditions the women who were selected as candidates for a therapeutic abortion tended to be the ones least likely to respond favorably to it. Their vulnerability to stress had already been demonstrated, and the psychiatrist had to weigh the relative stressfulness of continuing the pregnancy versus its termination. In either case the possibility of undesirable emotional reactions seemed considerable. At the other end of the spectrum, it has been reported that therapeutic abortion produces minimal or no emotional impact in women with no history of emotional disturbance (2).

In recent years legal changes regarding abortion have appeared with increasing rapidity in the United States and elsewhere, and abortion is becoming more and more a medically and legally approved procedure. Today's women less frequently must subject themselves to abortion under furtive, illegal, and emotionally distressing circumstances. Even so, adverse reactions may be inevitable. Peck and Marcus (3) reported some depressive symptomatology in 20 percent of the women given abortions for psychiatric reasons, in contrast to those whose abortions were performed because of rubella. Patt and associates (2) have concluded that aborted women may undergo a mourning process which coincides with the length of the expected pregnancy and produces some symptoms.

In this report we are comparing the overall reactions to therapeutic abortion in women who have a history of previous psychiatric illness with those who do not. This is an important area to scrutinize if we are to learn more about the natural history of therapeutic abortions and if psychiatrists are to be able to give informed opinions as to whether these abortions are indicated or contraindicated in specific instances.

METHOD

Detailed records were kept on patients applying to the North Carolina Memorial Hospital for therapeutic abortion on psychiatric grounds under the 1967 North Carolina amendments to the abortion law. Since these legal changes were made it has become necessary to certify only that continuance of the pregnancy threatens the health of the woman. In the vast majority of cases, in the absence of clear medical, surgical, or obstetrical contraindications to the pregnancy, such patients have been referred to psychiatrists for evaluation.

To the psychiatrist health is a holistic concept that comprises a woman's total emotional state, including her plans for the future, interpersonal relationships, self-concepts, and often her socioeconomic status. Indeed, in a previous study (4) of 207 women applying for therapeutic abortion, the most frequently cited ground for recommending the operation was the presence of some degree of depression; transient situational disturbance was the diagnosis in 41 percent of the women. It appears that most psychiatrists would prefer that abortion be available on demand. This is confirmed by polls, as we have demonstrated in an earlier paper (5). Meanwhile, some psychiatrists have continued to evaluate women for abortion and to provide the necessary certification while waiting for further legal progress.

From 1970 to 1971 we collected detailed questionnaire responses from many of the subjects from within a few weeks to two years after their abortions.

We sent letters to 301 women who were known to have

Revised version of a paper presented at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

patient: severe suicidal threats or attempts, a deteriorating social situation, or severe acting out with involvements with the law are typical examples. Under these circumstances, short-term hospitalization with active intervention along the lines mentioned by Dr. Adler may transform a failing into a successful long-range psychotherapeutic treatment.

There are some borderline patients who need long-term hospitalization as a crucial aspect of their treatment. The Psychotherapy Research Project of the Menninger Foundation found evidence that some borderline patients with particularly low motivation for treatment, severe ego weakness (manifested by lack of anxiety tolerance and impulse control), and particularly poor object relationships require an expressive psychotherapeutic approach with minimal limit setting or "structuralization" in the treatment hours and concomitant hospitalization with clear-cut limit setting and structuralization of the hospital experience. Patients treated with this approach achieved a high level of improvement, in contrast to patients with the same characteristics who were submitted to supportive psychotherapy (with limit setting and structuralization within the treatment hours) without hospital treatment of the kind mentioned.

In many cases, of course, a combined treatment approach such as the one I am proposing can be achieved without full hospitalization: partial hospitalization and/or other extramural or aftercare services can be provided, or the family can be supported to sustain the necessary limit setting. In general terms, the more severe the acting-out potential, the tendency to negative therapeutic reactions, or the suicidal or generally self-destructive trends, and the lower the patient's capacity for meaningful object relations, the more advantageous is an extended period of hospitalization concomitant with intensive psychotherapy. In our own hospital we have become increasingly optimistic about a treatment approach that combines extended hospital treatment with intensive, long-term expressive psychotherapy.

A pre-admission home visit evaluation led to the decision that this woman had a severe regressive potential at that point: she wanted a rest and wished to reject her children and boyfriend. Before admitting her the staff discussed with her a one-week inpatient stay, with later day hospitalization if necessary.

From the beginning the psychiatric resident and the rest of the staff attempted to clarify the problem this woman had in wanting so much, being disappointed, and in her fury self-destructively messing up her life. In spite of our discussing these issues with her and anticipating their recurrence on our unit, the patient became increasingly demanding, angry, and suicidal. While she was at home during a weekend after her first week of day hospitalization, she called the unit, stating that she was about to take a large overdose of a drug. The resident on call became angry with her when she refused to come back to the hospital; he thought of calling the police and discharging her to a state hospital. But in spite of his anger, he and a case aide made an emergency home visit.

In this home visit the two staff members felt they could not form an alliance with the patient to contain her self-destructive behavior; they sent her to the state hospital after telling her that the unit wanted her back but only after she could work out with the staff ways to put her feelings into words without acting on them self-destructively. A week later she arranged to see her therapist and negotiated an agreement to return to the unit as a day hospital patient. Although the six weeks of day hospitalization that followed were not tranquil, the limit setting and renegotiation were successful in establishing a working relationship with the unit.

CONCLUSIONS

The successful limiting of a patient's regression—in this case, self-destructive acting out—allows the patient and staff the opportunity to do the work it agreed upon: to explore in a safe setting some of the issues that brought the patient to the hospital and to clarify some of the patterns that the patient could not recognize before.

The essence of the treatment experience for borderline patients has been described by Winnicott (12) as one in which the patient has to learn that he cannot destroy the object or be destroyed by it, no matter how much he may wish this or fear it. The psychiatric unit that can struggle with its own retaliatory fury with such patients and can learn the value of nonpunitive limit setting is in a position to offer this kind of experience. The fact that these patients are expert in provoking the abandonment and destruction they fear places a burden on the staff that attempts to offer good treatment. The staff's response to the challenge of these patients determines whether they can offer the patients a new kind of experience or only a reconfirmation of the projections they are so expert in eliciting from people involved with them.

DISCUSSION

OTTO F. KERNBERG, M.D. (Topeka, Kans.)—Dr. Adler describes the characteristics of borderline patients derived from their predominant primitive defensive operations (splitting and primitive forms of projection—particularly projective identification, devaluation, etc.) and the effects of these primitive mechanisms and conflicts on the patients' hospital experience. These patients distort the interpersonal situation in terms of their intrapsychic conflicts, activate latent conflicts among staff, and contribute to inducing a temporary regression in the group processes—an important modality in short-term treatment units. Dr. Adler stresses the danger of permitting unchallenged regression to occur to such an extent that the acting out of conflicts within the hospital setting perpetuates the patient's gratification of pathological primitive needs. Dr. Adler also stresses the danger of excessive limit setting that obscures the patient's psychopathology. I agree with these points, and it seems to me that a clear structuring of the patient's experience on the unit and a systematic interpretation by the treatment team of the patient's behavior in the "here and now" are crucial aspects of the treatment of borderline patients.

What are the indications for the hospitalization of borderline patients, and what can be expected from short-term and long-term hospital treatment of them? Although a brief discussion does not permit full exploration of these questions, the following are some of the major diagnostic and therapeutic indications for short-term and long-term hospitalization.

Short-term hospitalization is indicated when the psychotic episodes that borderline patients may experience under excessive emotional turmoil, under the effect of drugs or alcohol, or in the course of a transference psychosis cannot be resolved within an outpatient psychotherapeutic setting alone. A well-structured hospital milieu program, clarification of immediate reality, and a combination of an interpretive psychotherapeutic and yet limit-setting milieu approach may resolve such temporary regression of borderline patients within a few days to a few weeks. Brief hospitalization is also indicated for those borderline patients whose chaotic life situation and incapacity to provide meaningful information to the psychotherapist make the diagnostic process itself (particularly distinguishing the condition from schizophrenia) extremely difficult and consequently hamper the planning of treatment. Short-term hospitalization is also indicated when acute life-threatening or other crises have potentially damaging long-range consequences for the

for the quarry. Not until the victim becomes aware of danger and tries to make a break will the chimpanzees on the ground leave their positions and converge on the fleeing baboon.

Meat is a delicacy for chimpanzees, and normally a great deal of excited calling accompanies the successful capture of prey. This attracts the attention of any other chimpanzees in the vicinity and they typically converge upon the hunters and cluster around, either watching intently or actually begging from the chimpanzees who have acquired shares of the carcass. When begging, a chimpanzee may hold his hand to the mouth of an eating individual in the hope that he will be given the remains of the mouthful (see figure 3), or he may hold out his hand toward the other, palm up, in the typical begging gesture of man.

Often begging behavior is rewarded. This is significant since food sharing among adults has not been recorded in any other nonhuman primate in the wild. After chewing for a while on a mouthful of meat and leaves (leaves are almost always eaten with meat) a chimpanzee will nearly always allow a begging individual to take it. Sometimes he will permit others to chew on the carcass at the same time as himself, or let them detach pieces for themselves. Occasionally he will actually tear off a piece himself and hand it to the one who is begging (6, 24, 25).

Tool Using and Tool Making

With respect to his tool-using behavior, the chimpanzee comes considerably closer to man than does any other living primate. Tool using in animals has always fascinated people because, for many years, man was typically referred to as *the* tool-using animal. A variety of animals (including invertebrates) do use objects as tools if we define tool using as "the use of an external object as a functional extension of mouth or beak, hand or claw, in the attainment of an immediate goal" (10). It should be emphasized, however, that tool-using ability in itself does not necessarily indicate any special kind of intelligence. The Galapagos woodpecker finch uses a cactus spine to probe insects from crevices in the bark. This is fascinating behavior, but it does not make this bird more intelligent than the ordinary woodpecker, which uses its long beak and tongue for the same purpose. The Galapagos finch employs a behavioral adaptation, the woodpecker a morphological one.

The point at which tool using in a nonhuman animal acquires significance, when viewed in relation to the evolution of tool use in man, is when a species or an individual within that species can adapt its ability to manipulate objects to a wide variety of purposes and, in particular, when it can use an object spontaneously to solve a completely novel problem. The chimpanzee has shown itself capable of using a wide variety of objects for a wide variety of purposes, both in the wild and in captivity. Moreover, if an object is not suitable for the specific purpose for which it is to be used, the chimpanzee will modify it accordingly, so that he may be said to show at least the beginnings of tool-making behavior.

Our research at Gombe has shown that one community of chimpanzees uses four different kinds of objects—grasses, sticks, leaves, and rocks—in a wide variety of different contexts. Sticks are used to plunge into ant or bee nests during feeding and occasionally as levers to enlarge the opening of such a nest. Sticks were used by chimpanzees to try and force open banana boxes at our feeding area. They may also be used during aggressive displays to intimidate other chimpanzees, baboons, or humans. One infant "clubbed" an insect on the ground. Grass stems are used when the chimpanzees are feeding on termites; they are also used as "investigation probes" to touch objects that the chimpanzees cannot reach with their hands or of which they are afraid. The end of the grass is then sniffed. Sticks and grasses may be trimmed to size and made more suitable in any of the above contexts. Leaves are used to wipe dirt off the body, and also as a "sponge" to sop up water in a hollow in a tree trunk when the chimp cannot reach the fluid with his lips. Here again the object is modified: before dipping the leaves into the water the chimpanzee crumples them by briefly chewing them. This makes his sponge considerably more absorbent and effective. Rocks are used as missiles during aggressive incidents and may be thrown forcefully and with good aim. One infant pounded an insect on the ground with a rock that he held in his hand. Once a chimpanzee used a twig to pick his nose; another individual used one to pick at something in her teeth.

There is not space here to detail the tool-using performances of laboratory- and home-raised chimpanzees, although some of them are very impressive. However, man is still the only primate to "make tools to a regular and set pattern" (26), and he is the only creature who relies on tools for his very survival (27).

Nonverbal Communication Patterns

Perhaps it is in the repertoire of postures and gestures which form the nonverbal communication system that some of the most striking behavioral similarities between man and chimpanzee are found. Chimpanzees may bow, kiss, hold hands, touch and pat each other, embrace, tickle one another with their fingers, bite, punch, kick, scratch each other, and pull out one another's hair. Not only do many of these movements look remarkably like many of the expressive postures and gestures of our own species, but the contexts likely to elicit the behaviors may be strikingly similar in the chimpanzee and man.

When an adult chimpanzee is frightened he may reach out to touch or even embrace another who happens to be nearby; this physical contact often has a calming effect on the gesturer. If both individuals were frightened, then both may be reassured. Similar contact-seeking behavior occurs commonly in man in stressful situations.

When two or more chimpanzees become suddenly excited—if, for instance, they suddenly come across a large amount of a favored food—they often exhibit intense contact-seeking behavior, embracing, kissing, holding hands, and patting each other, all while screaming loudly. Eventually they calm down sufficiently to start feeding. This behavior may be similar to that shown by a human child who, when told of a special treat, may fling his arms

around the bearer of good news. When peace was declared in London after World War II, the streets were full of people embracing, clasping hands, kissing, laughing, and crying.

After a young chimpanzee has been threatened or attacked, his need for reassuring physical contact with the aggressor is sometimes well illustrated. As he approaches the adult, still screaming, his behavior is tense; his limbs are flexed so that he is close to the ground and his movements are often jerky. As he gets close to the aggressor he may actually turn and move away for a few steps, but then he turns back again as his desire for contact apparently overcomes his desire to flee. When he finally reaches his superior he adopts a submissive posture, crouched close to the ground, still screaming and with his teeth and gums exposed in a wide grin of fear. In response the other chimpanzee will usually reach out and touch or gently pat the youngster, sometimes continuing for almost a minute until the subordinate quiets and gradually relaxes. Here again we find a similar pattern in man. In most societies people who have been quarreling will "make up" by means of physical contact, whether this be the cuddling and petting of a child or marital partner, or a more formal clasping of hands or brief pat on the back.

At this point I should like to emphasize that while the form of reassurance behavior looks very similar in man and chimpanzee—not only with respect to the gestures themselves and the context in which they may occur, but also in the relaxing effect of the physical contact on the submissive individual—the motivations underlying the behavior are probably quite different in man and chimpanzee. This is a fascinating and complex subject that I hope to discuss in detail elsewhere.

When two chimpanzees meet after a separation they may show gestures and postures that strikingly resemble some forms of human greeting. In such a context chimpanzees may bow, kiss, touch, or pat one another, hold hands, or embrace. A male may chuck a female or an infant under the chin. In chimpanzee society, reunion after separation often involves behaviors that serve to reestablish or emphasize the relative social status of the individuals concerned; originally, greeting behavior in man undoubtedly served a similar function. Indeed, this is still the case on some formal occasions, though human greeting behavior has for the most part become ritualized in our different cultures.

There are also similarities in the aggressive behaviors of man and chimpanzee. A quick upward jerk or a waving of the arm serves as a threat in both species, as may a level stare directed unwaveringly at a subordinate. A chimpanzee may adopt an upright posture when threatening and wave his arms above his head as he advances on the object that has elicited his aggression. He may throw objects overarm or underhand toward his victim. He may brandish a stick or make deliberate clubbing movements. Attacking chimpanzees may bite, hit, and kick their opponents. Female chimpanzees in particular sometimes scratch at and occasionally pull out handfuls of hair from their victims' heads.

THE UNIQUENESS OF THE HUMAN PRIMATE

It will have become apparent that even while I have been stressing the similarities between man and his closest living relative, many points of difference have been touched on. In fact, the longer I study chimpanzees and the more amazed I become at the extent of the behavioral similarities in the chimpanzee and man, the more I stand in awe of the gigantic evolutionary stride that our own species has taken in the last few million years. Let me very briefly enumerate a few of the characteristics that make man unique among the primates and that are highlighted by an understanding of the chimpanzee.

The chimpanzee has a wide range of calls. Each call is fairly reliably associated with some specific emotion—a scream usually signifies fear, a bark aggression, and so on. This means that the chimpanzee is able to communicate reasonably specific information about his feelings and his environment through the use of calls alone. But his repertoire of grunts and hoots cannot be compared with human language. Moreover, recent research into the speech centers of the human brain suggests that our language did not even originate from this type of primitive vocal communication.

The chimpanzee cannot convey information about the past and the future; he cannot pass on, through his vocabulary of calls, experiences of his own that might benefit his group or his species as a whole. It is true that recent work in teaching chimpanzees to communicate by means of sign language (28, 29) and with plastic word symbols (30) has shown convincingly that the chimpanzee is capable of a greater sophistication of mental process than most people were formerly prepared to accept, such as the ability to appreciate abstract concepts. But the chimpanzee intellect is dwarfed by that of a species that can produce a Plato, an Einstein, a Beethoven.

When the chimpanzee Washoe, trained in sign language, was shown herself in a mirror for the first time and was asked, in sign language, "What is it?" she signed back, "Me, Washoe." This suggests that the chimpanzee may show the beginnings of self-awareness. But man not only is conscious of himself as an individual being, he also questions the reason for his existence, he searches for clues as to how he came to be the way he is, he strives to understand his own behavior and the world and the universe in which he finds himself.

The chimpanzee, especially as a young adult, does show what might be considered the beginning of an affectionate heterosexual pair bonding: a male and a female may wander off together during the female's period of oestrus and sometimes for longer. At such times they may stay on their own, away from others of their kind (1). But this kind of relationship cannot be compared in any way with the tenderness and passion, the understanding and compassion, the exaltation and peace, that mark human heterosexual love in its highest form.

It is of interest that man has also leapt ahead of the chimpanzee in what we might call negative as well as positive intellectual evolution. Man can use language to the advantage of himself, his group, his species. With

words he can inspire others to acts of goodness and self-sacrifice. He can also use words to incite his fellowmen to deeds of evil and destruction. Despite his awareness of himself and of the individual existence of his fellowmen, and despite his understanding of the world he lives in, he can destroy not only human and animal life but the very environment that, as he alone among living creatures is capable of appreciating, enables him to live. Man, with his tremendous capacity to love, has a capacity to hate far transcending the worst of the squabbles that may break out between chimpanzees. Two neighboring communities of chimpanzees may occasionally indulge in displays of power as individuals hurl rocks and wave branches or even briefly attack one another. But they show nothing even remotely comparable to the horror of human warfare.

Today we are all aware of the tremendous need for a better understanding of our own species, yet only too often the scientist, searching for the biological basis of some human pattern of behavior, is confounded because intellect and culture have conspired to confuse the picture. We cannot afford to neglect any approach that might give us a better understanding of even a few aspects of man's evolution, his biology, his social behavior. And I believe the study of the chimpanzee is important in this respect.

And so we are continuing our intensive study at the Gombe Stream Research Center, where postdoctoral, graduate, and undergraduate students from the universities of Dar-es-Salaam, Stanford, Cambridge, and others are working as a team in our efforts to understand chimpanzee behavior more completely. Dr. David A. Hamburg is setting up a new facility at Stanford—"Gombe West"—where chimpanzees will be studied in groups in large outdoor compounds. Here we shall investigate problems that cannot be tackled in the field but that we know from our experience are relevant to the understanding of the behavior of the species. An initial area of inquiry will be the problems of adolescence; methods and goals will be closely linked not only with the research at the Gombe Stream but also with ongoing studies of human behavior. We hope that some problems arising in research with human subjects may be solved through work with the chimpanzees; in turn, work with chimpanzees may pinpoint areas of behavior that merit careful investigation in human subjects.

The study of the chimpanzee, with all his complexity of behavior and his close evolutionary relationship to man, is exciting and worthwhile in itself. If our research can help, even in the smallest way, in the better understanding of man, then our work will be even more rewarding.

ACKNOWLEDGMENTS

I should like to express gratitude to Tanzania's president, Mwalimu Julius Nyerere, to the prime minister, and to the many other government officials who have encouraged and assisted us in our work. The research was initially financed by the Wilkie Foundation and subsequently by the National Geographic Society, the Science Research Council, and the Wenner Gren Foundation for Anthropological Research; I should like to thank all these organizations. At present the work is financed by the Grant Foundation and I am particularly grateful to Dr. Douglas Bond, the president, and Mr. Philip Sapir, the director.

I could not have carried out the work in the field without the help of my husband, Baron Hugo van Lawick; I should like to thank him and also the many students and Tanzanian field assistants and helpers who have helped us collect an ever-increasing volume of information on chimpanzee behavior. I should also like to express my gratitude to the late Dr. L.S.B. Leakey, who gave me the opportunity to begin this research.

The Gombe Stream Research Center is now formally affiliated with Stanford University, thanks to the efforts of Dr. David A. Hamburg, and I should like to take this opportunity to express my deep gratitude to him for all that he has done in the past to stimulate our research at Gombe and for the exciting new research opportunities that his farsighted efforts are now providing at "Gombe West" at Stanford.

Depot Phenothiazine Treatment in Acute Psychosis: A Sequential Comparative Clinical Study

BY CHING-PIAO CHIEN, M.D., AND JONATHAN O. COLE, M.D.

In a study of the relative efficacy of three drug treatments for 46 newly hospitalized acutely psychotic patients, fluphenazine enanthate, alone or in combination with chlorpromazine, proved significantly more effective than chlorpromazine alone. Although fluphenazine enanthate, alone or in combination, produced more extrapyramidal side effects than chlorpromazine alone despite prophylactic antiparkinsonian medication, additional antiparkinsonian medication adequately controlled these side effects.

LONG-ACTING injectable fluphenazine preparations have been available to the practicing psychiatrist for several years. It is generally agreed that they have several important advantages over other phenothiazines (1–6). A single intramuscular injection every two weeks by a nurse obviously consumes far less nursing time than does the administration of oral medication once, twice, or three times a day. Many schizophrenic patients are unreliable about taking oral medication following their release from the hospital. Others become quite skillful at evading the actual ingestion of oral medication even while hospitalized. Injectable depot fluphenazine ensures that effective antipsychotic medication is being made available to the patient.

Although clinicians have expressed legitimate concern that a long-acting phenothiazine injection might lead to prolonged undesirable adverse effects, clinical experience and the literature do not suggest that a long-acting injectable form is any more likely to produce such side effects than is the oral form of fluphenazine. Serious hypersensitivity reactions have apparently not been encountered. Admittedly, long-acting injectable fluphenazine preparations cause a relatively high incidence of extrapyramidal side effects, but these appear to be adequately controlled by conventional antiparkinsonian agents.

Depot-type fluphenazine preparations, such as fluphenazine enanthate (FE), appear to be increasingly accepted both in the United States and in Europe for the treatment of ambulatory psychotics in the community and for treatment-resistant patients on chronic psychiatric services. To date, the outstanding advantage of this form of medication over all other phenothiazine medication has appeared to have been in the treatment of ambulatory chronic patients (1–5, 7–11).

In the psychopharmacologic management of newly admitted psychotic inpatients, depot fluphenazine has usually been administered after patients have stabilized on other more conventional oral phenothiazines. Patients often receive oral fluphenazine for several weeks before FE therapy is started in order to accustom them to the medication and to make sure that undesirable side effects do not occur. The use of FE as an initial treatment for acute psychotics has rarely been reported and, as far as is known, its efficacy has not been explored in a controlled fashion using conventional, nondepot-type antipsychotics for a comparison (12).

In clinical practice FE therapy in acutely psychotic patients is usually administered in combination with other antipsychotic drugs. This may be based on two factors: The clinician may feel insecure in giving only one injection every seven to 14 days during an acute psychotic episode, or he may believe that pharmacologically, more antipsychotic effect is needed than can be provided by a long-acting injectable phenothiazine alone. This practice warrants careful examination since Freeman's intensive review of clinical studies of combination medications led him to conclude that use of a single antipsychotic agent was as effective as any combination of antipsychotics or other drugs in the treatment of acute or chronic schizophrenia (13).

Preliminary uncontrolled use of FE alone in the treatment of acute schizophrenic episodes has led us to suspect that a long-acting injectable drug, administered alone, is a satisfactory medication regimen for the management of acutely psychotic inpatients. The extensive experience one of us (C.C.) has had with the use of this agent in chronic and aftercare patients has led him to respect both the drug's efficacy and its administrative and logistic advantages.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with Boston State Hospital, Boston, Mass. 02124, where Dr. Chien is Director of Clinical Research and Dr. Cole is Superintendent. They are also with Tufts University School of Medicine, Boston, Mass., where Dr. Chien is Assistant Clinical Professor of Psychiatry and Dr. Cole is Professor of Psychiatry.

This work was supported in part by Public Health Service research grant MH-16128 from the National Institute of Mental Health.

The authors wish to thank the staff of Dorchester Mental Health Center, Boston, Mass., and the staff of Douglas Singer Zone Mental Health Center, Rockford, Ill., for their assistance in this project.

The current study was designed to test the relative efficacies of FE alone, chlorpromazine (CPZ) alone, and a combination of the two treatments in newly admitted acutely psychotic patients.

METHOD

Subjects

The patients selected for study were all acute psychotics recently admitted to the two mental health centers where this project was carried out. All patients were judged to require antipsychotic medication by the clinical treatment staff. Both centers had a policy of treating psychotic patients as outpatients whenever possible. Thus it can be assumed that the patients in this study manifested intense, socially disturbing psychopathology. When the study was completed, 46 patients (24 men and 22 women) had been recruited for the trial. Their ages ranged from 17 to 62 years, with a mean of 36.8 years. Thirty-five patients (76 percent) received a diagnosis of schizophrenia, while nine patients (20 percent) were diagnosed as suffering from affective psychosis (depression), and two patients (four percent) from psychosis associated with organic brain syndrome (one associated with drugs and the other with alcohol).

Treatment Design

Upon their admission these acutely psychotic patients were randomly assigned to three treatment groups.

Group 1 (N = 16) received FE as the only antipsychotic medication. It was injected intramuscularly and at a dosage that could range from 0.5 cc. (12.5 mg.) to 3 cc. (75 mg.) at clinically determined intervals. Trihexyphenidyl HCl (Artane), 5 mg. twice daily, was given for five days after each injection to avert possible drug-induced extrapyramidal manifestations. Seven and one-half gr. of sodium amytal, injected intramuscularly, were administered as needed in the first 48 hours since FE was reported to take 24 to 36 hours to reach an effective blood level (14).

Group 2 (N = 15) received CPZ at an individually determined level, with both intramuscular and oral medication available to the treating physician. This group served as a control group (a standard treatment) since CPZ's clinical efficacy in the treatment of acute psychosis has been well established for more than a decade.

Group 3 (N = 15) received a combination of FE and CPZ, a common clinical regimen for acute psychotics at the two centers. Patients received FE in intramuscular injections of 0.5 cc. to 3 cc. at clinically determined intervals and CPZ daily. The dosage of CPZ and its manner of administration were at the discretion of the therapist. Trihexyphenidyl HCl was given prophylactically in the same fashion as in group 1.

At both centers, all patients involved in the study had their dosage regulated by the usual clinical staff. The research psychiatrist at each center scrupulously avoided influencing the amount or frequency of administration of antipsychotic medication used during the course of the study, except to specify that FE dosage should not exceed 75 mg. in a single dose. The dosage actually used therefore reflects a "clinician's choice" regimen based on the individual clinical judgments of different psychiatrists and psychiatric residents.

Evaluation

A form of sequential analysis was used because it appeared to offer the cleanest and most expeditious way of reaching an early, statistically valid assessment of the relative efficacies of the three treatments under study. A modified closed design, Bross's Plan A (15, 16), was selected for the present study because it would provide a test of statistical significance with a sample size of not more than 24 patients in each of the three treatment groups. A significance level of $p < .10$ was selected for the study because it would allow the achievement of an answer with the sample size previously noted and because it was felt that this level of significance would be clinically meaningful.

Each patient was rated after ten days of treatment, on a seven-point scale of global improvement, by an independent research psychiatrist who had no knowledge of the patient's medication. The decision to continue a patient on project medication beyond ten days was contingent on this global rating. If a patient was rated as "much improved" or "very much improved" he was considered a treatment success at that time and was discontinued from the study. At the same time, those rated as "much worse" or "very much worse" were considered treatment failures and were discontinued from the study. If the patient had an equivocal response, i.e., received a rating of "minimally improved," "no change," or "minimally worse," he was continued for another ten-day period of treatment and again evaluated. The decision to continue or discontinue was, as before, based on the outcome of the global rating. At the end of 30 days all patients were terminated from the study regardless of their rating.

For the purpose of the sequential plotting, patients who required the full 30 days of treatment and who were judged to be "minimally improved" or better were classified as treatment successes and those judged to be unchanged or worse were considered treatment failures. When a patient was discharged before the next evaluation date, he was followed on an outpatient basis until he completed the study. The psychiatrist responsible for the clinical care and medication of each patient in the study also rated the degree of improvement on a seven-point scale as long as the patient was in the study. His ratings were not used in the sequential analysis, but were used as an indirect way of comparing the independent research psychiatrist's rating with that of a clinician more actively involved in the patient's day-to-day management.

The Nurses Observation Scale for Inpatient Evaluation (NOSIE) (17) was used to evaluate each patient's ward behavior before the study and at ten-day intervals as long as the patient was in the experiment. The discharge rate within the 30 days with better clinical out-

come was also used as an indication of the efficacy of each medicine in the management of acute psychosis. For the evaluation of side effects, the NIMH form *Treatment Emergent Symptoms* (18) was used. There were no extensive laboratory tests since the drugs used in this study had been well investigated and had been reported to be clinically safe (11); however, routine laboratory determinations were performed on all patients at admission for monitoring purposes.

RESULTS

With three treatment groups to be compared by sequential analysis, three sets of comparisons—FE versus CPZ, FE versus FE and CPZ, and CPZ versus FE and CPZ—were carried out concurrently by plotting the preference sequence in Bross's Plan A graph (figure 1). The plotting procedure can be illustrated by using figure 1 as reference. The plotting line was moved one unit to the right each time a patient finished the trial. If a patient who was assigned to FE finished the trial with a rating of "much improved" or "very much improved" the plotted line moved obliquely upward toward the upper boundary; if this boundary was crossed, it would show the superiority of FE to CPZ ($p < .10$). If a patient failed to respond to FE (i.e., obtained a rating of "no change" or "worse"), the plotted line moved obliquely downward toward the lower boundary; crossing this boundary would show the superiority of CPZ to FE ($p < .10$). The same procedure was applicable to the patients who were assigned to CPZ, or to the combination of FE and CPZ.

Thus if the plotted line reached either the upper or lower boundary the study could be terminated, since one treatment would have been shown to be statistically superior to the other with only one chance out of ten ($p < .10$) that this superiority could have been due to chance alone. If the plotted line never reached the upper or lower boundary and instead reached the inner boundary, it was to be concluded that no statistically significant difference existed between the two treatment groups compared.

Comparison of FE versus CPZ. Thirty-one patients (16 from the FE group and 15 from the CPZ group) were required to finish the sequential comparison. As shown in figure 1, FE was superior to CPZ ($p < .10$).

Comparison of CPZ versus FE and CPZ. Twenty-seven patients (14 from the CPZ group and 13 from the combination group) were required to reach the significance level of $p < .10$ in favor of FE and CPZ over CPZ alone.

Comparison of FE versus FE and CPZ. Thirty patients (15 from the FE group and 15 from the FE and CPZ group) were required to end the comparison. Since the plotted line reached the inner boundary, no statistically significant difference between the FE group and combination group was demonstrated.

Total scores on the NOSIE scale, completed by research nurses at the two centers at the tenth study day, revealed significant improvements in ward behavior for patients in all three treatment groups, utilizing a paired t-test analysis. No significant differences among the three treatment groups in terms of net amount of change were revealed by single analysis of variance. Analyses of NOSIE scores at the 20- and 30-day periods were not carried out since a majority of the patients had completed the study after the ten-day assessment. The NOSIE scale, analyzed in this manner, appears to be less sensitive than a psychiatrist's global rating in revealing differences among the three treatments studied.

The following criteria were compared among the three treatment groups: 1) the average dosage of each treatment group, 2) the number of patients who finished the study at the first ten-day assessment, 3) the number of patients discharged from the hospital within 30 days after

†Every 11.2 days.

admission, and 4) the incidence of extrapyramidal side effects. Table 1 shows the average dosage of medication as follows: FE, 28.5 mg. every 11.5 days; CPZ, 388 mg. per day; and in combination therapy, CPZ, 349.6 mg. per day, and FE, 26 mg. every 11.2 days. Regarding the number of patients who finished the study by the first ten-day rating, there were only seven (47 percent) in the CPZ group who were rated as "much improved" or "very much improved," while 12 in the FE group (75 percent) and 13 in the combination group (87 percent) received this rating. This difference was statistically significant ($p < .05$). In other words, the long-acting FE, either combined with CPZ or alone, was associated with earlier clinical improvement than was CPZ.

It is noteworthy that more than 50 percent of the patients from each treatment group were discharged within 30 days after admission. This reflects the general philosophy of the two mental health centers that hospitalization should be avoided if possible or should be short-term if a patient's condition requires admission. The incidence of side effects, as expected, was highest among the groups who received FE, either alone or combined with CPZ. In the FE groups, five to nine patients (33 to 56 percent) showed extrapyramidal side effects, compared to only three (20 percent) in the CPZ group.

DISCUSSION

The findings from the present study thus indicate that a moderate dosage of FE at a moderate interval is superior to a moderate dosage of CPZ, at least during the first few weeks of inpatient treatment. The clinical result might have been different, of course, if the dosage of CPZ had been higher. However, the dosage for all drugs was left to the discretion of the clinician. Although a fixed dosage schedule in the research design might have answered any question about a specific dosage-related pharmacological effect, the present design provides clinical information based on common daily clinical practice.

The superiority of FE to CPZ could derive from one or more of the following factors: 1) a real pharmacological advantage, 2) relative unreliability of medication ingestion in the CPZ group, and 3) the dosage of the drug being used. It is difficult to determine which factor or factors contribute most to our results. In any event, FE alone or in combination with CPZ is clearly an effective treatment for acutely psychotic patients and is reasonably superior to CPZ at the dosages used at the centers where the study was conducted.

Since the combination of FE and CPZ was demonstrated to be statistically superior to CPZ alone with a slightly smaller number of patients (27 versus 31) than was the case in the comparison of FE alone and CPZ, the combination was very slightly more effective than FE alone. The difference is so small that it might well have occurred as a result of chance differences between the two treatment groups. In any case, our finding generally coincides with the conclusion of Freeman's intensive review (13) of combination versus single medications.

There was a somewhat lower incidence of extrapyramidal symptoms in the patients receiving the combination medications (33.3 percent) than in patients receiving FE alone (56.2 percent). Although it did not reach statistical significance, it may be worthy of note as a strong trend, since it is in a direction opposite to that which one would have expected. Could CPZ have had a mild antiparkinsonian effect? Similar findings were reported for the combination of CPZ with reserpine or trifluoperazine by several investigators (19–22). Cotzias and associates reported some improvement in eight out of 11 parkinsonian patients who received CPZ and ethopropazine, respectively (23). Thus they demonstrated an alleviative function of the phenothiazines in the parkinsonian syndrome. The anticholinergic property of some phenothiazines may possibly explain this alleviative function. If, indeed, CPZ has the dual function of both alleviative and causative effects of parkinsonian syndromes, this is certainly an intriguing area for future research.

The high incidence of extrapyramidal side effects ob-

served among the patients who were on FE, either alone or combined, despite the prophylactic use of an antiparkinsonian agent, raises a question about the utility of such a prophylactic practice. Five days of antiparkinsonian medication following each injection was prescribed in this study because of the common clinical observation that most of the extrapyramidal episodes occurred during the first few days after an injection of FE. The results observed, however, do not suggest any useful prophylactic effect and are compatible with the reports by DiMascio and associates (24, 25). In a separate study we conducted, a comparison was made among three groups who were all receiving FE. These three groups received: 1) antiparkinsonian medication daily, 2) antiparkinsonian medication for five days after each injection of FE, 3) antiparkinsonian medication as needed. This study also failed to support the validity of prophylactic use of antiparkinsonian medication.

In using sequential analysis based on global clinical judgment, one may question the reliability and validity of the evaluating psychiatrist's rating because "blindness" to the treatment conditions usually means minimum involvement with the patient. The blind rater had to evaluate the patient in a relatively brief interview (ten to 20 minutes). Since the blind rater agreed in 95 percent of the assessments with the staff who spent more time with the patient, the validity of a clinical global rating based on a relatively brief appraisal by a clinically experienced blind rater is affirmed. The sequential method used in this study might well be used in the clinical comparison of other treatments in psychiatry, with resulting economy in the number of subjects and rating time required.

SUMMARY

Despite the many encouraging reports of its maintenance use for chronic psychotic inpatients or less disturbed psychotic aftercare patients, the usefulness of depot-type FE for acute psychotic patients has rarely been reported, and its efficacy has rarely been compared with conventional nondepot-type antipsychotic agents. The present study was designed to explore the clinical efficacy of FE alone in acute psychotic patients, using CPZ as a standard control treatment. A third treatment, the combination of FE and CPZ, was also compared since this type of combined medications is often used in clinical practice.

A sequential analysis design (Bross's Plan A) was employed. This enabled statistically significant differences at the $p < .10$ level to be obtained after 46 newly admitted psychotic patients had been studied. Both FE and FE combined with CPZ were superior to CPZ alone at this level. The two treatments involving FE were not significantly different from each other. Although FE alone or in combination with CPZ produced a higher incidence of extrapyramidal side effects than did CPZ alone, despite the addition of prophylactic antiparkinsonian medication, these side effects were adequately controlled by the use of additional antiparkinsonian medication. This finding casts some doubt on the efficacy of routine prophylactic antiparkinsonian medication.

This study demonstrates that FE alone is a useful and effective agent in the treatment of newly hospitalized acutely psychotic patients. The addition of CPZ appears to do little to increase FE's therapeutic efficacy. At the dosage used (an average of about 350 mg. of CPZ per day), CPZ was significantly less effective than FE, either alone or in combination, in the treatment of acute psychotic states.

Schizophrenia: A Family's Projective Identification

BY JAMES R. STABENAU, M.D.

By means of projective identification, parents may contribute to the differential life course leading to schizophrenia in a family member. The author presents the case history of a family with a set of monozygotic male twins discordant for schizophrenia. The father, by suggesting that one twin was more vulnerable than the other, helped establish in that twin a negative identity, an inhibition (rather than a neutralization) of instinctual expression, and an aggressive (rather than libidinal) tie with the parents. The ego splitting that resulted seemed to be based on the child's projective identification in a pathologically defensive way.

NONGENETICALLY determined, enduring qualities of constitutional predisposition (Freud's "Congenital Ego Variations," Hartmann's "Innate Maturational Tendencies") were noted to be determinants in the process of differential parental expectancy and divergent states of ego development in childhood in a series of monozygotic twins. Clinical data were obtained from a detailed investigation at NIMH of a family with a pair of adolescent male monozygotic twins who were discordant for schizophrenia. Freud and Klein described the normative aspects of the projective identification process in development and indicated its defensive utilization in the psychotic state by a projective splitting of the ego (1, 2). Other data from the NIMH Twin Study (16 families) and Comparative Family Study (25 families) suggest that qualitative differences in projective identification by parents in relation to their children may be one of the processes contributing to the differential life course leading to schizophrenia (3–6).

THE ALLEN FAMILY HISTORY

The Allen family (all family names are fictitious) was referred as part of the NIMH series of monozygotic twins discordant for schizophrenia; it consists of the father, Joseph Robert Allen (a dentist), age 45; the mother, Helen Stanley, age 46; Anne, age 16; Kevin Robert (Robbi); his identical twin brother, Joseph Stanley (Stan), age 14; and Tobby, age 6. The twins were born one and one-half years after Anne, the result of a planned pregnancy. At eight months' gestation, there was fear that Helen Stanley might be pregnant with triplets, but "it turned out only to be two." Robbi was firstborn, weighing 6 pounds 12 ounces. His head had more molding than second-born Stan, who was delivered four minutes later, weighing 6 pounds 0 ounces. Robbi was noted as being "more drowsy" and "less alert," while Stan had "shining eyes."

Both were pink and responsive. From birth on, differences between the twins were observed by each of the parents, their sister, and friends. The family stated that Robbi was heavier in infancy and had a round face. He was more placid and easygoing and less alert, while Stan was lighter in weight, had a longer, tapered face, and was more alert. Robbi resembled the men in Dr. Allen's mother's family, that is, his ears "stick out." Robbi "was more easygoing and in less need for [sic] discipline than Stan. He was well behaved, but I like to see life in a boy [Stan] even though he's doing something wrong. It's better than a boy who's good because he feels he should . . . and who's not interested in anything [Robbi]." Robbi was "slower, less energetic or ambitious to undertake new things or explore," while Stan "grasps ideas more quickly and sometimes gets careless and overlooks things; Stan is more ambitious and more interested in trying new things. . . . Robbi wastes a lot of time alone in his room"; Stan was "more outgoing and sociable. Stan has more initiative. He got a morning paper route and worked it for a year, while Rob got a neighborhood evening paper route and gave it up quickly." Mrs. Allen noted:

> You can't help but have slightly different . . . well, each of your children are individuals even when they're identical twins; they're still individuals to you. Well, I mean you don't necessarily treat them like peas in a pod because they're not peas in a pod. They are different. You can love them all equally but that doesn't mean your reactions to each of them is the same. *Your* personalities are different, so naturally reactions are different.

Gifford and associates (7) have commented on the differences in size, behavior, and rate of maturation present at birth, presumably the result of differences in the intrauterine environment. These physical and behavioral

***Nonschizophrenic, monozygotic co-twin (C).

differences establish the original basis for certain individual characteristics in the developing ego of each twin. Although these differences are not genetically determined, they have some of the enduring qualities of constitutional predispositions (7).

DIFFERENTIAL EXPECTANCY

The NIMH group has substantiated the observations of Gifford and associates from retrospective data in a large series of one-egg twins (3). Review of the NIMH twin series of 14 pairs of monozygotic twins who were discordant for schizophrenia and of published accounts of life data from 86 additional pairs of monozygotic twins who were discordant for schizophrenia has yielded: 1) the following nine behavioral traits as characteristic of the pre-schizophrenic, pre-illness twin: submissive, sensitive, obedient-gentle, serious-worrier, dependent, well behaved, quiet-shy, stubborn, and neurotic as a child and 2) the following six physical traits as distinguishing the pre-schizophrenic twin: having had an illness of the central nervous system as a child, any birth complications, neonatal asphyxia, weaker, shorter, and lighter at birth. The criterion employed here was that the designated trait was present at least twice as often for the index twins as for the nonschizophrenic co-twins (see table 1).

Two items that appeared the most consistently in the 14 worldwide sources for these data were the pre-illness developmental description of the schizophrenic twins as more submissive (9.3:1) and more sensitive (7.6:1) than their co-twins. This range of psychobiologic "markers" may play a significant role within pathogenic families in helping to establish the selection of one twin as the more vulnerable and the one whose life course could be pathologically altered the most seriously. For 12 of the 16 pairs studied at NIMH to date the schizophrenic twins had a significantly lower birth weight (eight percent lighter than their co-twins). In addition, three of the four higher-birth-weight twins who developed schizophrenia were suspected of having a physical defect in the first three years of life, which served as a source for concern about that twin, indicating that "something was wrong" with him and not with the other. This was the

case with Stan and Robbi. Factors such as these may be the type of constitutional factors Freud mentioned as playing a role in the development of schizophrenia. Although nonspecific, they do connote a degree of vulnerability. This in itself may play a significant role in producing a deficiency in ego development.

If the establishment of an inner sense that something is wrong with the pre-schizophrenic that is not wrong with others is of etiologic importance in schizophrenia, it may be through establishing for the schizophrenic a negative expectancy, negative identity, or a defective sense of self-esteem. Jacobson referred to the assumption that the infant's earliest gratification-frustration experiences with the mother play an important part in stimulating perception and in promoting the process of differentiating the infant's self from the object world (8). Ritvo and Solnit (9) made the point that "equipment factors" in the child are important in determining what constitutes frustration for a particular child with a particular mother. Their patient, Margaret, demonstrated that when characteristics of the child interact forcefully with the deepest conflicts in the mother, adaptational difficulties of both the child and the mother are exaggerated and the close empathic tie with the mother, necessary for later identification, is hampered.

Robbi, like Margaret, demonstrated that the interaction of his "sensitivities" with his mother's anxious, ambivalent care (based on seeing the child as less alert) was characterized more by fearful uncertainty and discomfort than by the mutual satisfaction of mother and child. This mother-child atmosphere inhibited instinctual expression more than it facilitated the capacity to transform instinctual expression. The capacity in Robbi to neutralize was *not* facilitated, and neutralized energies were used for defenses (fearfulness, hesitancy, and so forth) and therefore were less available for adaptation. For Stan, who enjoyed a more secure and positive place in the mother-child relationship, the sequence led to a facilitated capacity to neutralize instinctual expression.

Neutralization has been described as the transformation of the energies of the instinctualized id into de-instinctualized energies that are subject to the service of the ego. Regressive behavior, including the psychotic process, may be an indication of deneutralization, while in the child with an ongoing process of neutralization, autonomous ego functions and supplemented activities emerge. Ritvo and Solnit concluded: "When internalization proceeds by way of a predominantly positive libidinal tie to the love object, it is more likely to proceed to completion than internalization that develops from a predominantly aggressive tie," and "the neutralization of libidinal energies as a result of identifications are more likely to make energy available for autonomous ego functions than identification proceeding from a predominantly aggressive tie to the object" (9).

PROJECTIVE IDENTIFICATION AND THE FAMILY

In this family Dr. Allen's self-image is closely tied to a competitive struggle with his older brother Kevin. He has always seen himself as comparatively weaker, less successful, less bright, more mischievous, "a black sheep," and more slow and plodding than his brother. Significantly, the problems that concern Robbi and his father reflect areas of unresolved personal conflicts or the repetition of problems the father experienced in growing up. Dr. Allen identifies the side of himself he likes or his ideal self-image with Stan, and he sees his negative qualities and "real" self-image reflected in Robbi. On the one hand he objects to parental influence in children's decisions; but on the other, he expresses concern about how the family should channel Robbi's interests. He values independence and initiative yet becomes upset when the child does not conform to parental expectations and requirements.

An excerpt from a conjoint family therapy session illustrates one aspect of projective identification in the relationship between Dr. Allen and his two sons.

> *Father:* "I don't . . . no, I'm not disappointed. All I think the boys should do is try and work harder. And I see traces of myself in both boys. That's why I don't . . . I see some things, if you're trying to compare, in both boys. I see that Robbi is hardworking and conscientious. I guess they're both conscientious for that matter. Robbi has been a little more aware of, I think maybe, of not being late for school. I was that type. I was very afraid to be late at school and I was hardworking and uh and uh . . . Robbi's . . . comparing myself to Robbi . . . and also that I didn't do well in track, of course, the same way . . . in high school. . . ."
>
> *Robbi:* "I'm doing fine."
>
> *Father:* "You're doing better than I did, that's right."
>
> *Mother:* "That bothers Rob when you say it like that—so that you're deprecating him. . . ."
>
> *Father:* "Actually . . . I told him I did worse than he did. I told him I did worse."
>
> *Mother:* "That's like saying he's not doing so good. . . ."

We learn that, additionally, Robbi compares himself unfavorably with Stan. A source for this appears to come from the father's indicating that Robbi has the qualities he dislikes in himself, whereas other qualities, which he admires, he finds in Stan. This type of splitting based on projective identification may be a significant source for the different self-image of each of the twins.

The Comparative Family Study of the NIMH Twin and Sibling Section has made a beginning toward delineating whether a differential expectancy based on projective identification may exist within a number of families (4). As described in the study, in six of 11 families of schizophrenics, the parents' ideal self-image was negatively correlated with their view of the index child, while it was positively correlated with their view of the control child. Of the five families of "normals," all correlations were positive except for one control sibling. This suggested for the parents of schizophrenics a negative-positive split in their view of the index and control sibling. That is, for the parents of schizophrenics, qualities that they described as being part of their ideal or self-image were seen as being present in the nonschizophrenic, same-sex child and absent from the schizophrenic child (see table 2).

* Pearson product-moment method.

** The mean correlation coefficient for each family was derived from the average of the following correlations: father's view of self and view of index child; father's ideal and view of index child; mother's view of self and view of index child; mother's ideal and view of index child.

*** The mean correlation coefficient for each family was derived from the average of the following correlations: father's view of self and view of control sibling; father's ideal and view of control sibling; mother's view of self and view of control sibling; mother's ideal and view of control sibling.

Both Freud and Klein have described the normative aspects of the projective identification process in development, as well as indicating that this process may be defensively used in excess, such as in a psychotic state where the process is characterized by a splitting of the ego of the individual (1, 2). The data from the NIMH Twin Study and the Comparative Family Study of Schizophrenia have suggested that the use of projective identification in the parents, relative to their children, may be one of the processes contributing to the differential life course of a schizophrenic family member (3–6). For the pre-schizophrenic child the negative quality of the projective identification utilized by his parents may lead to a predominantly aggressive rather than libidinal tie between him and his parents. This appears to contribute to impairing the child's ability to neutralize instinctual energy and this in turn leads to his utilizing projective identification in a pathologically defensive way that produces ego splitting. Such an individual further utilizes the projective distortion of reality as a means of handling the intrapsychic conflict that arises with increased aggressive and libidinal instinctual demands, which usually occur prior to the psychotic state.

The Allen family demonstrates this mode of splitting in projective identification. In his relationship with his sons, the father perceives in Stan and rewards him for the qualities that he sees as positive in himself (libidinal tie), while he admonishes and punishes Robbi for having the projected negative qualities that he disavows in his own personality (aggressive tie).

DEFENSIVE ASPECTS OF THE PSYCHOSIS

The nature of the intrapsychic conflict in Robbi was first verbalized in a conjoint family therapy session two years after contact was first made with the family at NIMH. During this session, Robbi described depersonalization, somatic delusion, and ideas of reference.

Robbi: "Well, let's see. In the first place, I started having them to some extent . . . I started having some sick thoughts, uh, not really too sick, but some sick thoughts from the seventh grade, and I was having sort of . . . a real tiny bit mentally disturbed in the seventh grade—well, I started being like this about a month before Georgianne's death (an adopted infant) and I don't think that that really had much to do with it because I was like . . . I started being like this before Georgianne's death, that that really didn't have that much effect on me anyway."

Therapist: "And up until 13 you had none of this, except partly in the seventh grade?"

Robbi: "Well, I might have had a little bit, in certain cases, a little bit sensitive and stuff like that, but I will say in seventh grade I suffered mentally—mentally in the sense that if anyone did something to me, I would be terribly sensitive to it and I would take it very much to heart and things like that, and I thought things like in the seventh grade people are really mean to each other; people are really bad. Well, for one thing . . . right now . . . I'll discuss some of the feelings I have right now . . . uh . . . that everything . . . this may sound sort of crazy but I feel like everything that is me is sort of up in my head because that's where all the . . . all the strain and everything else is going on and that's a feeling I've had for a long time.

"So I've had this belief for several years, and I thought that Dad and Stan also had this physical defect, and I guess you'd call it and let's see . . . and let's see. Well, anyway the reason why he thinks I get this idea is because . . . because . . . because I have trouble talking to people and stuff like that. I used to think just about every couple of seconds of my life I thought about that fact—that there was something wrong with my mouth. Every couple of seconds of my life and right now I think of it an awful lot too. When I say things, I read meanings into what people say and also into what people do, see, and so sometimes when I say something like, 'That rug is gray,' well, then I mean . . . I get this idea that it's sort of poetic, sort of, and it means something else like—anything. I guess you know what I mean, like it has a hidden meaning like, 'That rug is gray' is sort of a code to say something else."

Thus Robbi described through ideas of reference a series of symptoms including an early concern that there was something wrong with him, all of which indicate an effort to cope defensively with the intrapsychic conflict.

Regarding significant differences between neuroses and psychoses Arlow and Brenner concluded that:

In the psychoses instinctual regression tends to be more severe and more pronounced than in neuroses. Pre-phallic fixations and conflicts over derivatives of these drives are particularly prominent.

In the psychoses conflicts over aggressive impulses are more intense and more frequent than in the neuroses. Because of these impulses that patient has a special need to protect the object from his own aggression. As a result, serious disruption in the patient's relationship with external objects and the environment are likely to be prominent.

In the psychoses disturbance of the ego and super-ego functioning are more severe than in neuroses. The disturbances in functioning may be due to faulty endowment, maldevelopment, or regressive deterioration as a consequence of conflict (10).

Beres, from a study of deviant children, indicated how "certain developmental traumata in specific cases in childhood may leave the ego vulnerable to later progressive involvement. Such conditions of ego vulnerability may facilitate ego regression in a manner similar to the way in which instinctual fixation may lead to instinctual regression" (11). Robbi was considered to have "something wrong" with him in the early neonatal oral period; thus the choice of a delusion concerning a distortion or deformity of his mouth may be related on one level to this "trauma" during the oral stage. On the other hand, a level of symbolism in Robbi's somatic delusion appears to relate to his father's drilling in people's mouths as a dentist and to be an elaboration of an aggressive, though sexualized, tie with his father through a combination of oral incorporation and aggressive drilling.

The authors I have cited here and others have pointed out that the weak ego of the psychotic patient is not able to counteract the regressive reinstinctualization of functions that had previously achieved a high degree of secondary autonomy. Consequently, intrapsychic conflicts become overwhelmingly acute, and the ego is forced to resort to extreme measures of defense. Chief among these is the regressive alteration of ego functions. The extreme forms of denial, projection, isolation, and introjection that Robbi exhibited are also typical of the ego's defense armamentarium in psychosis.

Although the term "projective identification" is primarily used to describe a level of early object relations, when the young adult or adult individual splits off and projects good and bad parts of the ego onto external objects, which then become identified positively or negatively with the parts of the self projected in the other, it is viewed as a mechanism of defense. This defense is utilized to a greater degree in the schizophrenic state and apparently to a lesser, although significant, degree by the nonpsychotic parents of schizophrenics, as noted in their relations to their children.

SUMMARY

From this case study and the NIMH Twin and Comparative Family Studies it appears that certain physical, temperamental, or developmental attributes serve as a focal point for the projection of parts of the parent's negative self-image onto the child. The projected features appear to be dissociated, repudiated, negative elements from the parent's personality or representative portions of repudiated, introjected objects from the parent's own life. The negative quality of the projective identification utilized by the parents of the pre-schizophrenic appeared in this case to have led to a predominantly aggressive, rather than libidinal, tie between the parent or parents and the child, as compared to his same-sex sibling or cotwin. This may have contributed to an impairment in the ability of the pre-schizophrenic child to neutralize instinctual energy, a decreased adaptive and coping capacity, and ego splitting produced by pathologic defensive use of projective identification in the pre-psychotic or psychotic state.

The Private Practice of Community Psychiatry

BY WARREN T. VAUGHAN, JR., M.D., DONALD E. NEWMAN, M.D., ALLAN LEVY, M.D., AND SAMUEL MARTY, M.D.

The successful incorporation of the private practice of psychiatry into a system of community mental health care was attributable to several factors. They included an affluent catchment area; support from hospital administration and staff, private mental health practitioners, and a state-county finance program; and attempts to eliminate schisms that have traditionally separated private and public sectors of psychiatry. The success of this program has implications for the development of mental health services in the 1970s.

THIS IS AN ACCOUNT of the successful development by private practitioners of a comprehensive community mental health center at Peninsula Hospital and Medical Center, Burlingame, Calif. The center serves a four-city catchment area of 94,000 persons 15 miles south of San Francisco. It has developed a full spectrum of services including mental health consultation and education and private-office-based outpatient services as well as center-based inpatient, emergency, and partial care services.

The catchment area contains relatively few disadvantaged ethnic minority families or individuals. The 1970 census reported more than 2,500 persons with Spanish surnames in the catchment area, but only several hundred Orientals or blacks. The hospital district embraces a wider area than the assigned catchment area, comprising a total population of more than 200,000 persons. A California hospital district is a public agency that raises money by taxation and bond issues for capital construction and equipment costs. Patient care and treatment itself must be paid for at cost through other revenue sources, such as private funds, insurance, Medicare, Medicaid, and CHAMPUS (Civilian Health and Medical Program of the Uniformed Services).

In June 1963 the executive committee of Peninsula Hospital's professional staff appointed an ad hoc committee on psychiatric services and asked one of us (W.T.V., Jr.) to serve as technical consultant and co-chairman of the committee together with the chairman of the department of medicine. The committee's task was to develop a plan for full inclusion of psychiatry into the professional services of Peninsula Hospital. A year later, in July 1964, a 12-bed inpatient unit called the Mental Health Unit was opened, with one of us (D.E.N.) serving as director.

In August 1964 the first meeting of the psychiatric section of the department of medicine was held, attended by the seven psychiatrists then on the professional staff of the hospital. In the fall of 1964 funding for mental health centers became available under federal community mental health center legislation; and in December 1964 representatives of the hospital began to meet with the Mental Health Division of the San Mateo County Department of Health and Welfare to explore the possibility of developing a comprehensive community mental health center at Peninsula Hospital. A preliminary plan was drawn up that provided a wide range of community-based services incorporating ideas and principles such as accessibility, continuity of care, and collaboration with other professionals—principles painstakingly developed by mental health planners in the 1950s and early 1960s (1–5). In March 1965 the staff psychiatrists at Peninsula Hospital voted to take responsibility for developing a comprehensive community mental health center, and the board of directors of the hospital district voted to proceed with plans for a center in conjunction with the building of a new eight-story wing.

A construction grant application, approved by local health groups, was submitted to NIMH later in the year. It was accompanied by a resolution from the County Board of Supervisors expressing their intention to contract with Peninsula Hospital District to provide comprehensive mental health services to the communities yet to be designated as the catchment area for the new mental health center.

DEVELOPMENT OF SERVICES

The center opened in March 1969. In June 1969 the professional staff voted bylaw changes establishing a department of psychiatry and an affiliate membership to the professional staff for licensed clinical social workers and psychologists in private practice. The new department of psychiatry organized itself with an executive committee and a number of other committees including committees on medical audit, proctorship, utilization re-

The authors are with Peninsula Hospital Community Mental Health Center, 1783 El Camino Real, Burlingame, Calif. 94010, where Dr. Vaughan is Chief of Community Services, Dr. Newman is Director, Dr. Levy is past Chairman of the Department of Psychiatry, and Dr. Marty is now chairman of the Department of Psychiatry.

view, research and new programs, and continuing education.

The center was awarded a staffing grant beginning September 1969, and in October 1969 it began providing a full range of psychiatric and mental health services to its designated four-city catchment area under provisions of a $500,000 contract with the San Mateo County Department of Health and Welfare. The new center became the service center for region II of the county's new regional center program. Indirect services to the catchment area, comprising community organization work, mental health consultation, and education, have been paid for under the contract. Direct patient care and treatment is paid for by a number of means, one of which is full or partial payment for hospital care and professional services for financially eligible individuals and families under the county contract.

California's Short-Doyle Act, as amended in 1969, provides the legal and fiscal means for contracts with private providers, such as ours with San Mateo County.

From January through December 1971 the center provided 8,451 days of inpatient care to 956 persons. Of these, 180 came under the county contract and 282 under Medicaid or Medicare. The remaining 494 patients had private insurance or other coverage. During 1971 the center provided 12,390 sessions of partial care to 1,592 patients, of whom 566 were covered by the county contract and 545 by Medicaid or Medicare. The remaining 481 patients had insurance or other private means. Fifty-seven percent of these patients and 77 percent of the partial-care patients were from the designated catchment area. A total of 1,173 patient visits were made to the psychiatric emergency service, which is staffed by a specially trained crisis intervention team and an attending psychiatrist on call 24 hours a day. Sixty-three percent of these visits were made by patients within our designated catchment area.

The center delivered 6,820 sessions of individual, group, and family therapy to 899 outpatients in private practitioners' offices under the provisions of the county contract. Indirect services, provided primarily by salaried center personnel, included in 1970–1971 more than 600 hours of staff time spent in consultation and education work with elementary and high school personnel. Monthly group meetings with school psychologists and guidance personnel, police and probation workers, and the clergy were developed during 1970–1971. We are now expanding our concept of indirect services to include such programs as a teen-age drop-in center and parent education programs.

A citizens advisory committee was established by the hospital board of directors in 1969. By the spring of 1971 it had become effectively organized and played a vital role in mobilizing citizen interest and support at the time of a serious mental health budget crisis, which for a time threatened the center's county contract. In December 1970 the hospital board purchased an adjacent office building, which it has remodeled to provide a social milieu and group therapy center for the treatment of children, adolescents, and their families. This new facility opened in the summer of 1971. The citizens advisory committee has responded to these developments with the establishment of two subcommittees—a subcommittee on children and youth services and a subcommittee on financing and long-range planning.

By July 1971 the center had survived its first two years and its first major crisis. The professional staff had grown from the original seven psychiatrists to 45 attending psychiatrists and 45 affiliated nonphysician licensed mental health practitioners. To the basic question, "Can a group of private practitioners join together to develop and run a comprehensive community mental health center?" we can now report, "yes." The fact that this is possible seems to us to be of extraordinary importance as we move during the 1970s into: 1) the further development and strengthening of community-based programs of care and treatment for psychiatric patients, 2) the development of new arrangements for payment for services under government-sponsored plans as well as private insurance and other prepayment plans for groups of individuals and families, and 3) the implementation of preventive psychiatry through community action and collaboration with other professionals and agencies concerned with families and children.

Every patient at our center has a private attending mental health practitioner. He is paid on a fee-for-service basis for services to patients under the contract, with the hospital district serving as fiscal intermediary, much as Blue Shield serves in this capacity for Medicare. We have developed a center intake and referral service for the catchment area that, in addition to the emergency service, serves as a bridge between the center's salaried professionals and the private practitioners who assume clinical responsibility for all patients. Patients can come into the system at various levels of care—for emergency services, inpatient admission, and outpatient consultation. They can receive services with a minimum of delay and with built-in continuity of care.

In February 1971 the professional staff voted to set up a peer review committee for prior authorization and utilization review of all cases in which the hospital bill and professional fees were being paid for in whole or in part through the county contract. The need for this became apparent by October 1970, when we found that contract funds allocated to the catchment area were being spent at a much too rapid rate when there was minimal case monitoring by the center itself. One year's experience of reviewing over 263 cases involving more than 65 private practitioners indicates on the whole a very positive response on the part of the practitioners.

The usual administrative approach to case review, involving impersonal third-party intrusion into clinical practice and the therapist-patient relationship, has been replaced by a focus on developing a balance between clinical needs and financial realities in a case conference atmosphere, with development of treatment plans linked to explicit treatment goals. This experience has many implications for other groups of private practitioners who may group together as a hospital staff, or in medical or psychiatric societies or foundations, to take responsibility for

contracted mental health services to designated groups of people.

FACTORS CONTRIBUTING TO SUCCESS

We can readily identify four factors that have contributed to the success of the center.

1. Peninsula Hospital is located in an affluent community with well-established patterns of private health care delivery. This factor has undoubtedly contributed to the success of the center; however, it does not mean that this private practice model cannot also be used in less affluent areas.

2. The professional staff and hospital administration supported the development of the center. A public hospital district is a rather small administrative unit; in contrast to a large county or state administrative structure it has a capacity for administrative flexibility that maximizes its ability to innovate in program development, use of personnel, and staff development.

3. We have a favorable manpower situation and an interested citizenry. A decade of pioneering in community mental health services for San Mateo County has successfully reduced the stigma surrounding mental health care and has developed a felt need within the community for services close to home. This has resulted in an influx of well over 100 private mental health practitioners to San Mateo County since 1958, most of them interested in the development of a broad spectrum of community-based direct and indirect mental health services (6).

4. We must take special note of the presence of a state-county program for mental health services, which is financed by a state-county contribution of funds on a 90 to ten basis and which makes possible such contract services as ours (7, 8).

These favorable conditions certainly now exist in other communities in California and across the nation. In our opinion, however, they are not sufficient in themselves for the creation of a mental health center along the private practice model. In addition, at least four familiar schisms in professional practice must be bridged. They are as follows:

Schism I: Isolated private office practice versus closed-staff private psychiatric hospital practice;

Schism II: Office practice of psychiatry versus traditional medical practice centered in general hospitals;

Schism III: Private fee-for-service office and hospital practice of psychiatry versus public psychiatric services in hospitals and clinics with salaried professional personnel; and

Schism IV: Patient-centered psychiatric treatment services versus community-centered mental health promotion and preventive services for specific population groups.

Privately practicing psychiatrists have welcomed the opportunity to become members of a "community of professionals" based at the general hospital. In the 1950s and early 1960s, private patients who required hospitalization were usually referred to one of several private sanitariums in the community. Patients without financial means were referred to the county hospital or directly to the state hospital. These institutions, with traditionally closed staffs, took complete medical and psychiatric responsibility for the patient until he was returned to the community.

This situation (schism I) contributed to breaks in continuity of care for psychiatric patients despite encouragement by the private sanitariums and public services for the referring physician or psychiatrist to follow his patient during the course of hospitalization. Thus private psychiatrists welcomed the opportunity to attend their own patients in a therapeutic milieu (mental health unit) in the general hospital, with easy access to professional colleagues, both psychiatric and nonpsychiatric, and ease of involvement of patients and relatives in the therapy program. For these psychiatrists the private sanitariums and state hospitals have thus become a valuable resource for selected patients, and the general hospital setting has become a new resource suited to a wide spectrum of individuals in need of a short-term stay in a therapeutic milieu as part of their treatment.

There has traditionally been a wide schism (schism II) between the general medical and the psychiatric communities, with minimal use of psychiatric consultation and referral and, after referral, little continued involvement of the nonpsychiatric physician in treatment and planning for aftercare. It was this schism that led the physicians at Peninsula Hospital and Medical Center to enthusiastically support the establishment of an inpatient psychiatric unit in the hospital and to insist that nonpsychiatric physicians be allowed to admit patients to the unit for the social milieu and group psychotherapy provided by the center. Strong feelings were expressed that the inpatient unit should not adopt the tradition of separate inpatient and outpatient attending physicians and therapists (schism I) and that it should avoid the nonpsychiatric physician's lack of involvement (schism II).

Communication between psychiatrists and nonpsychiatric physicians has greatly increased at Peninsula Hospital since 1964. Many more consultations occur, with psychiatrists visiting such areas as emergency services, intensive care, coronary care, orthopedic rehabilitation, and pediatrics. Psychiatrists who had rarely left their offices now attend staff meetings, see patients in the hospital as consultants, and, of most importance, are continuing to treat their regressed patients with the aid of a team of mental health professionals in a therapeutic milieu. An increasing number of nonpsychiatric physicians have learned how to work with the therapeutic community and have remained with their patients, thus providing continuity, support, and remarkably good aftercare planning. At times this has been a slow and painful process, but it is important to note that *there has been no alternative to collaboration available.* No one else will take responsibility for the patient except the admitting physician and other attending physicians who may be called in by him, the patient, or the family.

Psychiatrists have been acutely aware of the isolation between the private sector and public mental health ser-

vices and of the existence of two patient care systems, public and private, at the state level as well as at the local level (schism III). Feelings have been strongly expressed by our psychiatrists that there should be one standard of care, care close to home, and continuity of care. There should be a broad range of community services available to everyone regardless of financial status, adequacy of health insurance, or severity of illness. Our goal has become one of eliminating the indigent patient concept and separate facilities for persons who receive public financial assistance for needed psychiatric care. With our system of fee-for-service with third-party payments, financial eligibility and manner of payment become more simply a matter of concern only to the finance office.

There is a single facility and standard of care for all in the community. We can thus avoid the long waits in clinic corridors and impersonal responses familiar to many in years gone by—conditions that remove from patients their dignity and sense of personal worth. The feeling of self-worth incorporated in our system can be seen as an essential element of our treatment program, and it probably explains in part the acceptance of our approach by the users and the community as a whole.

Indirect mental health consultation and education services and the involvement of the community in direct services through collaboration in many joint endeavors and at many different levels are now serving to bridge schism IV, the gap between mental health professionals and other human service professionals in the community.

IMPLICATIONS FOR THE 1970s

The fact that a comprehensive community mental health center can be developed by private practitioners gives us hope that mental health programs and psychiatric patients can indeed be included in first-class programs and as first-class patients in a national health plan. Third-party payments for services rendered, accountability through peer review, and fiscal responsibility and periodic audit of clinical and community programs with the application of cost-benefit analysis will highlight health care services in the 1970s. We submit that private practitioners can develop community-based clinical and community services that meet these requirements for health care delivery in the 1970s. Furthermore, the cost is no more and perhaps will prove to be significantly less than the cost of comparable services provided by public clinics and hospitals.

We hope that other communities of professionals will join in similar efforts to develop new types of mental health delivery systems, which can use the skills and interests of the increasing number of privately practicing mental health professionals across the country.

Problems Associated with the Introduction of a Psychiatric Unit Into a Rural General Hospital

BY SANFORD BLOOMBERG, M.D.

The author describes the establishment of a psychiatric unit in a rural general hospital in Massachusetts and some of the problems that arose in the first two years; particular attention is paid to the interaction between the psychiatric unit and the hospital's medical staff. Emphasizing psychiatry as a medical specialty and attempting to relate psychiatry to traditional medical values were vital in coping effectively with the problems.

THE ESTABLISHMENT of a psychiatric unit in a rural Massachusetts general hospital in September 1969 met with many challenging problems. Conflicts emerged in the clinical, administrative, and social aspects of hospital and community functioning. This paper will confine itself to discussing the interaction between the psychiatric unit and the medical staff of the hospital. Resolution of the problems arising out of this interaction is continuing; it involves concepts of professional identity, differences in social consciousness between psychiatric and other physicians, and what may be termed a generation gap between a relatively young multidisciplinary mental health team and an older, traditional medical staff.

THE SETTING

Greenfield, Mass., is the county seat for an area of about 750 square miles with a total population of 60,000. The hospital is a private, nonprofit voluntary general hospital with 215 beds in a town of 18,000. Prior to the establishment of the psychiatric unit, the hospital staff's contact with psychiatry had revolved around one psychiatrist in the immediate area whose duties included directing an alcoholism clinic and a state-supported mental health clinic. The active and courtesy medical staff at the hospital consisted of 62 physicians, most of whom were overworked. The administration of the hospital, supported by a lay board of trustees, was more progressive and community oriented than an important segment of the medical staff. Some of the younger physicians on the hospital staff had been trying without success to induce recent medical school graduates to come to Greenfield. The nearest major medical center was 100 miles away in Boston.

From its inception the psychiatric unit was based on the concept of the therapeutic community (1, 2). Individual therapy, group therapy, psychodrama, and occupational-recreational therapy were offered within a context of utilizing the total social structure of the unit. Emotional distress was seen primarily as the result of interpersonal and social experience. A knowledge of intrapsychic dynamics was constantly used in planning individualized treatment and in clinical decisions, but group and interpersonal interaction remained the focus in therapy. A multidisciplinary mental health team shared responsibility for directing daily activities and managing the patient group; patient participation in decision making occurred only in certain selected areas. Through a system of clinical and supervisory conferences, medical responsibility for the therapeutic program always prevailed. However, this medical direction was not always clearly recognizable to those accustomed to more traditional medical models of responsibility and decision making (3).

PROBLEMS IN INTERACTION BETWEEN PSYCHIATRISTS AND OTHER PHYSICIANS

Almost immediately after the establishment of the psychiatric unit, friction was noted in the matter of requests by psychiatrists for consultation with nonpsychiatric physicians. These physicians were invited to consult on the psychiatric unit concerning medical complications observed during the psychiatric patient's stay in the hospital. The purpose of these consultations was to bring experienced medical care to the patient. It was also hoped that more frequent contact between the medical staff and the psychiatric staff would make each group more comfortable with the other.

But the results of these consultations were unsatisfactory. Within a few months nonpsychiatric physicians, especially general practitioners in the older age group, began ignoring requests for consultation. It was apparent

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Bloomberg is Director, East Spoke, Franklin County Public Hospital, Greenfield, Mass. He is also in private practice at 112 Washington Ave., Northampton, Mass. 01060.

that the environment of the therapeutic community caused them discomfort. In addition, contact with patients who were severely disturbed or withdrawn seemed to interfere with these physicians' medical judgments. The nonpsychiatric physicians as a group also felt that requests for consultation regarding minor medical conditions did not warrant their taking time from their busy schedules. On the other hand, the psychiatrist showed his reluctance to deal with medical problems, which for years prior to his assuming the position as director of the psychiatric unit he had shunned in his office practice.

Difficulties between the personnel of the psychiatric unit and the medical staff also emerged during the transmission of orders from the consulting nonpsychiatric physician to the psychiatric nurse. Members of the nursing staff of the psychiatric unit had been encouraged to contribute to discussions of the care and management of psychiatric patients at clinical and supervisory conferences. During inservice training conferences nurses had been urged to ask questions concerning the rationale of medical orders and the psychiatric direction of chemotherapy and psychotherapy—in fact, the entire treatment program. When the family physician would order medications and give other instructions concerning the management of medical conditions that might be at odds with a patient's psychiatric treatment plan, the nurses would ask the physician about possible untoward side effects. Some physicians who had an authoritative approach could not tolerate what they interpreted as a challenge to medical judgment. In addition a nurse, because of her own need to control and manipulate, sometimes provoked a justifiable objection by a physician to her interference with his medical prerogatives. The unit supervisory system dealt immediately with such personality problems, but there was no such vehicle to deal with the irate physician.

Another area of disagreement in the relationship between the unit and the medical staff was the objection of the family physician to the requirement that he relinquish psychiatric management of his patient to the director of the psychiatric unit. At times a close relationship, developed over many years, had to be interrupted when the care of a patient with an acute psychiatric disorder was assumed by the psychiatric staff. The classical family physician-patient relationship was not effective in dealing with psychiatric problems that demanded an approach which the family physician, because of lack of training or personality structure, was not capable of. Many general practitioners refused to give up their control and continued to admit their psychiatric patients to the hospital's medical service. The underutilization of the psychiatric unit during its first year was demonstrated by the fact that 131 patients were admitted to the unit while 156 patients with a primary psychiatric diagnosis were admitted to the general medical service.

Needs of a nature that could not be met by older physicians were seen especially among the younger patient group. A significant number of young people coping with identity problems demonstrated symptoms indicating their struggle to resolve ambivalent feelings and thoughts about the environment in which they found themselves. The therapeutic community was especially helpful in the resolution of such conflicts. But grave concern arose in the minds of older, traditional physicians when the values and attitudes so important to them were subjected to open discussion and often rejection by patients in the psychiatric unit. Authoritative advocacy of standards of any kind was incompatible with the encouragement of self-assertion, independence, and autonomy within the ground rules of the psychiatric unit. Several physicians became convinced that a referral to the psychiatric unit was a prescription for emotional and political license.

The rationale for short-term stays on the psychiatric unit was another source of misunderstanding. The unit was part of a comprehensive community mental health center, which included among its components a state hospital 20 miles away. The role of the general hospital psychiatric unit in the total program was diagnosis, crisis intervention, and disposition. The therapeutic community program was designed to educate patients to deal with a crisis in their lives during a relatively brief separation from their families. Instituting marriage counseling, family therapy, and individual psychotherapy succeeded in returning most patients to their homes in one to four weeks. Other patients requiring a longer period of hospitalization to become involved in a therapeutic program remained on the unit up to three months. Patients with chronic, intractable characterological or psychotic conditions requiring periods of hospitalization longer than two to three months were transferred to the state hospital or to a private psychiatric hospital 25 miles away.

Distinguishing between the indications for long-term and those for short-term hospitalization was difficult enough for the staff of the psychiatric unit (4). For family physicians, with vague concepts of emotional disorder, the differentiation made by the psychiatric staff appeared arbitrary at times. Physicians who had developed a close relationship with their patients considered a recommendation for hospitalization in a long-term facility an abandonment of the patient. In addition, the concept of limited treatment goals and a return to the community of chronic patients with irreversible impairments in ego function was troublesome to some physicians.

Structural and Program Changes

The alienation between the psychiatric service and the medical services found an opportunity for expression in areas less directly related to patient care. For instance, the structural and program changes implemented by the administration affected other departments in the hospital, including radiology, electrocardiography, pathology, and the ambulatory care unit. Familiar routines, office locations, and rounds were significantly altered. A group of internists was allowed to renovate an old building adjacent to the new hospital structure and move their private offices onto the hospital grounds. Renting office space to private practitioners on hospital grounds was a radical departure from a policy of noninvolvement by hospital authorities in the private practice of medicine. Rancor at these changes and inconveniences was not infrequently

UNIVERSITY OF MEDICINE LIBRARY

displaced onto the fact that the psychiatric unit was there.

The discomfort was further provoked by the role diffusion in the psychiatric unit's therapeutic community: functions previously identified with psychology, social service, and nursing as separate disciplines were frequently shared and exchanged among these disciplines. Patient and staff participation in decisions about leaves of absence, discharges, and modes of therapy was equally disquieting to physicians who felt a threat to their omnipotent role in patient management. The concept of psychiatric supervision of other mental health disciplines and the delegation of responsibility for patient contact and treatment were novel in their experience. Psychiatric-medical supervision and responsibility were exercised firmly but so unobtrusively that they seemed nonexistent to physicians accustomed to issuing peremptory orders to nurses on hospital medical wards. The values and mode of operation with which the physician had always identified himself seemed to be cast aside within the therapeutic community.

Another major area of conflict for those members of the medical staff who looked askance at psychiatry was the issue of therapeutic abortion. In the year preceding the establishment of the psychiatric unit, two therapeutic abortions for psychiatric indications had been performed. In the year following the psychiatric unit's entry into the hospital, eight therapeutic abortions were performed. Psychiatry was associated in the minds of opponents of such procedures with a breakdown of morality and the loss of medical control of a medical procedure.

A movement toward stiffening the hospital regulations on therapeutic abortions gained ground. A recommendation was made to change the requirement of three consultations with staff physicians, with two affirmative consultations needed for therapeutic abortion, to four consultations with unanimous approval. The president of the medical staff appointed a committee that included the director of the psychiatric unit to study the matter. The frequently observed difference between psychiatrists and nonpsychiatric physicians in personality structure and in social and political attitudes again became clear (5–8). Psychiatrists' awareness of the cultural, sociological, and political factors in the issue was considered irrelevant or in opposition to the conviction of conservative physicians that the physician alone must control the decision for medical procedures such as abortion. Attempts to differentiate psychiatric indications from psychiatric reasons for therapeutic abortions also were met with skepticism (9). The psychiatric unit became identified with the "liberal" view of therapeutic abortion.

EFFORTS TO DEAL WITH THE PROBLEMS

The difficulty encountered in inviting general practitioners onto the psychiatric unit was reduced as the psychiatrist became more comfortable in treating minor medical ailments and in ordering diagnostic laboratory procedures to rule out significant medical disease before requesting consultation from nonpsychiatric physicians. The tendency then developed to call on physicians in the medical specialties rather than on general practitioners; the comfort and cooperation of the specialists, especially the internists, had always been remarkable compared to that of the general practitioners. In addition, the psychiatrist called for a review of the consultation policy throughout the hospital in order to exert some pressure on other physicians to respond to fewer but more appropriate psychiatric requests for consultation. The result was a reasonably satisfactory resolution of the consultation problem.

In its second year of operation, the psychiatric unit expanded to a second floor. Sixteen beds remained in the therapeutic community, and 12 beds on the second floor were designated for patients whose problems had been shown from experience not to respond to a therapeutic community. A more traditional, less intensive psychiatric milieu was created. Nonpsychiatric physicians were encouraged to maintain primary responsibility for their patients while consultation with the psychiatry, psychology, social work, and nursing services was made available. In addition, patients with psychiatric problems who were recovering from surgery or who had concomitant physical conditions requiring treatment were considered appropriate candidates for the second floor; their treatment was the responsibility of their attending physician.

In the second year of operation, with the addition of the second-floor program, 328 patients were admitted to the psychiatric unit, 58 patients were admitted to the second floor and cared for by their attending physicians, and 162 patients with a primary psychiatric diagnosis were admitted to the general medical services by their own physicians. A significant factor in the increased utilization of the psychiatric unit was the greater community acceptance of the unit and the enlargement of its catchment area.

The problem of the differences in personality and social outlook between the psychiatrists and the other physicians, as demonstrated in the treatment approach to younger patients, was more difficult to solve. This area was closely related to the mode of operation of the therapeutic community, which seemed to threaten the nonpsychiatric physician's value system and professional identity. Members of the therapeutic community staff were encouraged to become more tolerant of the value system of the medical staff. Unjustified and personally determined challenges to medical prerogatives were handled directly and firmly in supervisory conferences. Efforts to educate the medical staff about the drug scene, the youth culture, and the unobtrusive but definite medical responsibility for the therapeutic community program were less successful. Weekly inservice training sessions and a clinical staff conference were instituted for this purpose. Both were unsuccessful. Lectures and discussions in which psychiatric jargon was used held little meaning for the medical staff. Physicians who attended frequently led the discussion into medical matters that were meaningless to the nonmedical staff present. It was clear that to be effective, any education program for physicians had to be conducted with a medical orientation and termi-

nology, and had to be carried on without the presence of nonmedical personnel.

These efforts were discontinued. The psychiatrist began a campaign of informal hospital corridor meetings, socialization at a weekly coffee hour for doctors, attendance at medical staff meetings, and personal explanations to those physicians who appeared to have been disturbed at their experience on the psychiatric unit. The goal of educating most of the physicians about the purposes and expectations of the psychiatric unit seemed to be reached. During periods of socializing, discussions frequently took place about the drug scene, the youth culture, and psychiatric supervision of nonpsychiatric personnel to carry out treatment within their ability and training. The physicians who had been most persistent in their negative attitudes remained on the periphery of these exchanges. But a wider and wider circle of goodwill and mutual understanding began to develop. No-fee psychiatric consultation in the general hospital and outpatient evaluation for patients of the medical staff were offered. Consultation and evaluation notes and letters were designed as devices to teach about psychiatric disorders and about the psychiatric unit's program. Evidence emerged that the nonpsychiatric physician was gaining an understanding of the differing indications for short-term and long-term inpatient hospitalization and for outpatient treatment.

Little more than a discrete neutrality in the intrahospital struggles for power over policy changes was thought appropriate for the psychiatric unit. The threat to medical omnipotence posed by the delegation of responsibility to nonpsychiatric personnel was partly reduced by the measures already described. In addition, nonmedical personnel were encouraged to communicate changes in psychiatric management to nonpsychiatric physicians. The contacts emphasized the fact that the program was directed by a psychiatrist. The increased personal contact also helped relieve the discomfort each group felt with the other.

In dealing with the matter of therapeutic abortion, psychiatry's identification with the medical profession came into question. But the experience on this psychiatric unit overwhelmingly argued for inclusion of mental health within a total health care system. Mixtures of physical and emotional problems were so frequent that to divorce psychiatry from medicine was unthinkable. In order to maintain an identification with medicine, an effort was made to understand and relate to "traditional medical values, concepts of illness, role definition, and institutional lodgment" (10). Psychiatry, operating within a comprehensive community mental health program of which this psychiatric unit was a part, was seen not as an innovative force in our society but was represented in its traditional role as a medical specialty. To take any other stance, it was thought, would be to make psychiatry's continued identification with medicine extremely difficult. In the controversy over whether to make a therapeutic abortion more difficult to obtain, the psychiatrist took the position that abortion on demand was a social and political question, to be decided by legislative and judicial action (11). Notice was served that on this unit psychiatry would not be used to bring about social change. Adherence to psychiatric indications for abortion within existing law would be the criterion for recommending therapeutic abortion, and economic and social reasons for abortion would not dictate a positive recommendation. The effort to adopt a stiffer regulation of therapeutic abortion in the hospital failed when put before the full medical staff. After weeks of discussion, the regulations were in fact liberalized to state that the interruption of pregnancy for psychiatric reasons required consultation with one psychiatrist and only one other physician.

It is difficult to measure the effect of this controversy on the relationship between the psychiatric unit and the medical staff. It may perhaps best be described by the impression that physicians previously hostile to psychiatry became at least somewhat unsure of the basis of their hostility, and physicians of a more progressive stamp looked upon the psychiatrist as conservative. Physicians in between these groups had no apparent change in attitude. The psychiatrist certainly felt his medical identification more strongly then ever. The markedly increased utilization of the psychiatric unit by both the community and the rest of the general hospital seemed to indicate that psychiatry was being better accepted by a large part of the medical staff.

Hospital Treatment of Borderline Patients

BY GERALD ADLER, M.D.

Staff members handling hospitalized borderline patients are challenged to offer them a new kind of experience rather than reconfirming the projections they are so expert in eliciting from people. The author describes an approach to treatment of these patients in which the staff attempts to handle its own retaliatory fury toward these patients because of their provocative behavior and is able to set limits in a nonpunitive way.

AN INCREASING LITERATURE is accumulating about the treatment of the borderline patient (1–6), clarifying the characteristics of this group of patients and broadening our understanding of the many problems that arise in their treatment. Many authors recognize that behavioral regression is a major danger in the hospital treatment of borderline patients (3, 6). This paper will discuss issues related to the hospital treatment of this group and focus on the patients' regressive potential, which can be especially manifest during hospitalization. It will also attempt to clarify why these patients often arouse intense feelings in the hospital staff. Such feelings can result in situations in which limit setting may be presented in a punitive, destructive way to the patient and the staff's wishes to work with the patient can end disastrously, with the patient viewed as bad, willfully misbehaving, and not worthy of further treatment. The dynamics of staff interaction in response to these patients that can lead to these results will be examined.

The word "borderline" is used to describe patients with a stable personality organization (5) as well as those who are in transitory states between neurosis and psychosis. In this paper I am referring to a group of patients who have certain fixed personality characteristics and who maintain an adequate capacity to test reality except under severe stress, when they can become transiently psychotic (1, 3, 5). When functioning optimally they exhibit many neurotic-level strengths. However, under stress, their overwhelming rage following a disappointment can lead to the emergence of primitive concerns of abandonment and mutual destruction. They often handle their fury in self-destructive, masochistic ways. They have low self-esteem, in part because of their primitive guilt, and tend to project this feeling of badness onto the world. They often see people as objects to gratify their needs, yet have extremely punitive superegos that torture them for their devouring wishes and fury.

They frequently describe feelings of emptiness, hopelessness, and helplessness. In part this is a result of their conviction of their own badness as well as a lack of a capacity to keep the image of good experiences with good objects within themselves. In contrast to many schizoid and schizophrenic patients, these individuals are often able to form rapid, intense, engulfing relationships from which they expect a great deal and are almost invariably disappointed. Hospitalization can be the stress that can lead to disorganization and behavioral regression since it can provide intense relationships, promise so much implicitly, and ultimately disappoint. The regressive behavior may include the emergence of clinging, demanding, and whining in relationships as well as negativism, along with self-destructive concerns and actions.

The increasing literature about these patients may be a result of the fact that more people with serious character disorders, many of whom can be classified as borderline (7), are appearing for treatment. In addition, there has been a great increase in well-staffed psychiatric units that can offer these patients intense relationships with staff members. In contrast to the barren, understaffed state hospital image, modern treatment units can provide the stimulus of a large pool of available staff members arousing expectations of immense gratification followed by fury, disappointment, and the behavioral regression already described.

Because these patients exhibit so many areas of strength and may appear to be psychoneurotic when they are first seen, the beginning of a behavioral regression is often interpreted by the staff as willful misbehavior: the patient is seen as a bad child rather than as an overwhelmed patient under great stress. The regressive behavior may occur only with staff members who most arouse their patient's longings, disappointment, and fury, further supporting the staff's contention that the patient is misbehaving. They may also arouse envy in the staff, who observe these patients as acting out their feelings of entitlement to receive unending gratification on their own terms. In addition, the patients are often expert at devaluing and provoking staff members and making

them feel helpless (1, 2). The staff may ultimately feel furious and helpless in a situation where their every attempt to be helpful is rebuffed as the patient appears more regressed, demanding, helpless, hopeless, suicidal, and self-destructive. The staff response is often a retaliatory fury, resulting in the punishment of the patient when limit setting is attempted.

PROJECTIVE IDENTIFICATION AND SPLITTING

It is particularly important to understand the staff's tendency to punish these patients, since the impulse to punish is nearly unavoidable in anyone working with them. In addition to the reasons I have already described, projective identification and splitting are important phenomena that occur in the ward setting of patient-staff interaction. In projective identification, the patient attempts to get rid of a part of himself by placing it into an object, which may then persecute the patient. At the same time the patient feels depleted and empty (8). Another aspect of projective identification is that the patient has to expend much effort and activity to control the person who is the recipient of the projected part of the patient; if the patient does not control this person, he then feels in danger of being overwhelmed by the part projected onto that person (5).

The relevance of this discussion of projective identification to the staff's tendency to punish these patients is as follows: staff members, when they are the recipients of projected parts of patients, tend to act like those projected parts. I do not mean that they receive projections in a literal sense but that they react to the fantasied projections of the patient because of complex factors: 1) the staff member responds to the projected part empathically since it reverberates with a similar but more submerged and often less destructive part in himself and 2) the actions and interactions of the patient with the staff members tend to provoke a response in the latter (especially around the patient's need to control them) that brings this submerged part of the staff members to the surface, with the tendency for it to be acted upon.

Splitting is related to projective identification. In the phenomenon of splitting, positive aspects of the patient that are separated from his negative aspects (both are derived from positive and negative internalized interactions with early objects) are projected onto different people (5). On a psychiatric unit, different staff members may be the recipients of different split parts from the patient. As described above, different staff members will tend to act toward the patient in ways consistent with the fantasied projection they receive from the patient.

The implications of projective identification and splitting are profound. Staff members who are the recipients of cruel, punishing parts from the patient will tend to react to the patient in a cruel, sadistic, and punishing manner. Staff members who have received loving, idealized projected parts of the patient will tend to respond to him with a protective, parental love. Obviously a clash can occur between these two groups of staff members. These mechanisms also help to explain why different staff members may see the same patient in very different ways.

It is an important observation that people who usually function on a high level of integration in many areas can feel and act in regressive ways in group settings, especially when there is a lack of structure or a breakdown in the group task (9, 10). In the hospital setting, this observation is consistent with the experience that staff members have the tendency to act empathically on projections they receive from patients. Since patients can project different parts onto different staff members, an internal drama within the patient can become a battleground among the staff. And amazingly, staff members begin to act toward one another as if each one of them had the only correct view of the patient and as if the part the patient projected onto the other staff members were the only true part of those staff members. In addition, staff members compete to be the positive part of the patient's splitting; they can also be quite distressed to find themselves the recipients of the negative parts.

A Vignette

A brief vignette illustrates aspects of these complex mechanisms of patient-staff interaction. At a staff meeting a series of angry outbursts occurred among nurses, social workers, and occupational therapists about who would be responsible for supervising cleaning up after a family night (which involved dinner and a discussion group for patients, their families, and staff members). Repeated accusations and recriminations from one staff group to another centered around the feelings of each discipline that the others really did not care about them and did not really understand the burden of work they had, especially on the day that family night occurred. Interpretations of the personal problems of staff members began to appear. The heated discussion ultimately led to a detailed account about the specifics of clean-up.

It then became apparent that although the patients had agreed to assume responsibility for the preparation of food, serving, and clean-up, they tended to disappear during the day and after the meeting, leaving much of the actual preparation and clean-up to the staff. Instead of supervising, staff members were cooking and scrubbing pots. It became clearer that the staff members were fighting with each other while forgetting the origin of their problems, i.e., their difficulties in working with the patients. The patients were not expressing any direct anger about their reluctance to fulfill their agreed-upon participation in family night and their simultaneous wish to be cared for and fed by the staff. In its meeting the staff was oblivious to this reality. Instead they showed massive anger toward each other for not caring or doing enough for each other. Another factor was that the staff was uncertain how they felt about new programs such as family night, and about the importance of program changes to patients and their families.

Stanton and Schwartz's classical work (11) defined the deleterious effects of covert staff disagreement on patient care in hospitals. I have attempted to amplify their observations by clarifying how the primitive defense mecha-

nisms of borderline patients tend to bring about and accentuate overt and covert disagreements within the staff; this can lead to the staff's doing to the patient what the patient may fear most.

THE NECESSITY FOR SETTING LIMITS

How can we define and describe the requirements for successful hospital work with these patients, who have serious regressive potential? A major requirement is a unit's capacity to set limits empathically without punishing the patient, while clarifying with the patient and staff the complexities of patient and staff interaction. I have stressed these patients' expectations of so much in every situation and their ultimate disappointment, fury, and regression. The therapeutic environment must anticipate this occurrence and define a structure involving the unit as a whole and the staff participation on this unit.

A short-term unit, which is defined as such to the patient before his admission, directs itself toward limiting the "total-gratification" fantasy of these patients. Yet this alone is usually insufficient in a group of patients who are able to ignore and avoid facing reality when under stress. The staff therefore has the task of rapidly evaluating the patient and family, including a definition of the problem and recognition of the diagnosis of the patient and his regressive potential; a therapeutic approach that addresses itself to this potential must then be formulated.

This approach acknowledges the defects in the patient's observing ego, his incapacity to maintain distance about problems when he is overwhelmed, and his tenuous capacity to form a working alliance with the staff. But it also addresses itself to the expectation that these capacities can slowly be achieved. The evaluation of the patient will almost always give evidence of repeated expectations, disappointment, and self-destructive behavior following the disappointment. Staff members can help the patient see that this has been a pattern in his life and raise the question of whether he might repeat such a pattern as part of his hospitalization (7). Many patients can acknowledge this possibility when they are not approached punitively by the staff. The acknowledgment can become the first step in a tentative alliance between patient and staff to explore and anticipate early evidence of the repetition in the hospital. They can also explore the means by which a new kind of experience can be facilitated that includes the patient's increasing capacity to tolerate delay and his ability to put into words feelings that previously would be expressed by flight or regressive behavior.

Limit setting becomes an important part of any unit working with borderline patients. For in spite of everything I have outlined, many such patients will begin to regress in ways that staff definition and redefinition of the problems will not touch. In addition, many of these patients have had early experiences with parents who either literally abandoned them as children or were alternately abandoning and smothering (1). They spend much of their lives attempting to get the caring they feel was absent at significant times early in their lives, yet they provoke those they wish to protect them to punish and abandon them instead. Those who end up in the correctional system turn to society through its courts and prisons for controls. Those who choose the "mental illness" route can put a psychiatric unit to the test as to whether the unit can firmly protect and care, or whether it too will punish and destroy. The success or failure of limit setting on a psychiatric unit can depend on staff vigilance to control the tendency to punish and reject rather than to limit the behavior of the patient in a way that can become a corrective emotional experience.

Limit setting can also include discharging or transferring a patient who cannot be managed on the unit as well as helping him pay attention to the realities of his life: his family, friends, and work. Family meetings and home visits can help with these realities. Depending upon the staff's control of its tendency to be punitive, the limit-setting experience can be a rejection of the patient or a step in defining with the patient how the staff and patient can work together and, if a transfer to another hospital or discharge is necessary, the beginning of a negotiation leading to a successful readmission. As already discussed, the demands and projections of these patients can lead to much splitting and angry disagreements among the staff members. Although time-consuming, frequent staff meetings can be crucial in developing trusting relationships among staff members so that patient projections and distortions can be readily recognized for what they are. It is particularly important for staff members working with these patients to know each other very well so that there is no question in a staff member's mind where another staff member stands on certain issues. When one staff member can think about another: "He could not possibly have said to this patient what the patient tells me," then he is in a position to avoid a situation of potential splitting and help the patient negotiate appropriately with the staff and even look at the nature of his distortion. Staff meetings also provide an opportunity for the staff to discover and evaluate incidents of overt or covert punitiveness toward these difficult patients.

CASE REPORT

I now want to illustrate how a difficult borderline patient taxed a psychiatric unit and almost succeeded in getting the unit to reject her angrily.

Case 1. The patient, a 25-year-old unwed mother of two small children, threatened to cut herself when her boyfriend of five years, who was the father of her children, threatened to leave. Her history included rejection by an aloof mother who sent her to an aunt for several years, and a father who drank and was emotionally unavailable. Since the age of 17 the patient had had repeated but brief state hospital admissions for wrist cutting, precipitated by the termination of relationships with men. She had not been hospitalized for the four years she had lived with her current boyfriend, although their relationship had been stormy and recapitulated aspects of her relationships with her parents.

Rubidium: Biochemical, Behavioral, and Metabolic Studies in Humans

BY RONALD R. FIEVE, M.D., HERBERT MELTZER, PH.D., DAVID L. DUNNER, M.D.
MORTON LEVITT, PH.D., JULIEN MENDLEWICZ, M.D., AND ANN THOMAS, M.S.

A growing body of experimental evidence indicates that rubidium possesses unique neurophysiological characteristics in animal systems, suggesting a need for investigating its antidepressant potential in humans. Lithium, an element in the same periodic series, has been used successfully in the treatment of mania. A number of studies have demonstrated that rubidium and lithium have contrasting behavioral, EEG, and biochemical properties. Over a period of 20 to 86 days, five depressed patients received varying doses of rubidium chloride, up to a maximum of 370 mEq. retained. No immediate or long-term side effects were recorded in this preliminary dose range. Behavioral and metabolic data are presented for these patients, along with a discussion of the safety factors.

RUBIDIUM, discovered in 1861 by Bunsen and Kirchhoff, is one of the Group 1A alkali metals belonging to the same periodic series as lithium, sodium, potassium, and cesium. It is widely distributed in mineral deposits and can be extracted from lepiodolite and carnallite rocks, which are also the major sources of lithium. The atomic weight of rubidium is 85; one of its isotopes (Rb^{86}) has been used extensively in tracer doses in medicine.

Rubidium is found in virtually all biological systems. Physiologically, rubidium most resembles potassium, and these two elements have a great degree of metabolic interchangeability.

The introduction of rubidium into human therapy (in the 1880s) as the bromide for epilepsy and the iodide for syphilis did not escape notice in the medical journals of that period. Thus, there exists a surprisingly comprehensive literature covering not only a 30-year history of the administration of rubidium to humans, but also an earlier body of animal and in vitro experimentation that laid the groundwork and provided the rationale for its introduction into clinical medicine.

Even without reviewing the early animal studies on rubidium emanating from the laboratories of Grandeau and Bernard in 1864 (1), Ringer in 1882 (2), Richet in 1382 (3), and Botkin in 1885 (4), it is apparent that numerous eminent physiologists and chemists from the 1860s to the 1880s worked enthusiastically with this new element.

PREVIOUS CLINICAL EXPERIENCE IN HUMANS

The first documented use of a rubidium compound in human therapy was with rubidium chloride, used by Botkin in St. Petersburg (Leningrad) in 1877–1888 on ten acute cardiac cases. Botkin reported his work in his doctoral dissertation, written under the supervision of the noted physiologist Ivan Pavlov and presented to the Imperial Biomedical Academy at St. Petersburg in 1888. Rubidium chloride was administered orally to humans with daily doses of approximately 1.6 gm., up to a total of 300 mEq.

The general effects observed in most patients were a slowing down of the pulse rate and an increase in blood pressure. Botkin attributed these effects to a direct influence of rubidium chloride on the centers of the vagus. Also observed several times was a notable improvement in the patients' subjective sense of well-being. At least 60 other well-documented trials of human rubidium therapy occurred in the late 1880s (5–8).

The whole 50-year history of the introduction of rubid-

Read at a New Research session at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

This study was supported by the Office of Research of the New York State Department of Mental Hygiene.

ium into human therapy has left curiously little trace at all in the records of medicine. The numerous researches into rubidium in the post-1918 period have not only concentrated entirely on animal experimentation in vivo and in vitro, but they appear to have no awareness that the element had ever been used previously in human therapy.

As far as we can tell from surveying the entire foreign literature of this period, no one ever died from taking rubidium; and, as reported by its users, it produced no surprising or irreversible side effects. If we take into account the number of well-known specialists who prescribed it in the large clinics during the 30 years of its medical use, rubidium was probably taken in one of its compounds by upwards of 1,000 people. Together with its potassium counterparts, it was finally phased out of medicine, not through any serious physiological disadvantages but simply because less empiric and more effective treatments completely outdated it.

Today, at the possible introduction of a new role for rubidium, its earlier and generally forgotten performance in medicine is certainly worthy of rescue from oblivion. It is noteworthy that the 1940 edition of *The Merck Manual* (9) still listed rubidium compounds in recommended dosages for use as an anti-epileptic, as a hypnotic, for nervous afflictions, and for external use in optic neuritis and conjunctivitis.

REDISCOVERY OF RUBIDIUM IN MODERN TIMES

Rubidium and lithium have contrasting behavioral, EEG, and biochemical properties. The first discovery of this in modern times was made by Meltzer and associates (10), who reported that rubidium increased the prevalent frequency of the EEG in monkeys and altered the behavior in the direction of increased activity. This group of authors went on to suggest that rubidium, like lithium, might therefore have application to modern psychiatric therapy, particularly in the affective disorders. Lithium, in contrast, had been shown to produce a slowing of the EEG in manic and nonmanic patients in studies reported by Platman and Fieve (11) and by Mayfield and Brown (12). These studies were soon followed by the biogenic amine studies of Stolk and associates (13), which indicated that rubidium enhanced the turnover of norepinephrine in rats whose biosynthesis of norepinephrine was inhibited.

The data of Stolk and associates suggested that greater amounts of neuronally stored norepinephrine were released by rubidium to central adrenergic receptors. In this study, the disappearance rate of labeled norepinephrine was increased by rubidium treatment, while concentrations of labeled normetanephrine increased up to fivefold in the rats treated with rubidium, as compared with controls. In contrast, previous studies with lithium had shown opposite effects, in that lithium appeared to increase the uptake of norepinephrine into synaptosomes (Colburn and associates [14]) and increase the intraneuronal metabolism of norepinephrine, as reflected by a decrease in normetanephrine with an accompanying increase in both deaminated and deaminated-methylated metabolite fractions (15, 16). These changes induced by lithium were interpreted to reflect a decrease in the concentrations of active norepinephrine at transneuronal receptors.

Stolk and associates (17) have since demonstrated that rats treated with daily doses of rubidium chloride showed increased levels of shock-elicited aggressive behavior when compared with controls treated with potassium chloride. Lithium, in contrast, was shown by Sheard (18) to decrease shock-induced aggression in rats, thus providing a comparison of the effects of these two salts on a common behavior.

In an independently performed behavioral study by Eichelman and associates (19), the effects of rubidium on shock-elicited aggression were likewise evaluated. This study sought to determine whether the rubidium effect was related to the cationic properties directly or to an effect on monoamine metabolism, since 6-hydroxydopamine also increases shock-induced aggression. Rubidium carbonate increased shock-induced aggression after 14 to 16 days of treatment, whereas cesium chloride failed to produce a similar effect. With rubidium treatment, the primary change was a 300 percent increase in norepinephrine turnover, whereas with cesium chloride the treated animals showed an increase in serotonin turnover of 40 percent, without major norepinephrine or dopamine changes. These authors concluded that the differing effects on brain amines of cesium and rubidium tend to implicate norepinephrine, rather than dopamine or serotonin, as a putative neurotransmitter in the behavior of shock-induced aggression. Rubidium, the authors concluded, thus seemed to be specific in altering norepinephrine metabolism and did not appear to affect serotonin metabolism, when administered in doses sufficient to cause aggression in rats without apparent toxic effects.

Of further importance are the balance studies of Relman and associates (20) in the 1950s, which indicated that when rubidium is fed to animals it replaces intracellular potassium mEq. for mEq. Relman and associates noted that when the total body burden of potassium in animals is replaced by rubidium to the extent of 40 to 50 percent, the animals become aggressive and hyperactive and finally go into convulsions and death.

Because the behavioral, biogenic amine, and EEG changes produced by rubidium can be described as "opposite" to those produced by lithium, and because rubidium appears to primarily affect intracellular potassium metabolism while lithium has its major effect on sodium metabolism (21), we hypothesized that rubidium may have an application in the research and therapy of the affective disorders or other psychiatric conditions. Despite the fact that rubidium salts were given to a number of patients in the 1880s, the medical observations collected at that time do not provide sufficient information to meet the legal and ethical requirements of contemporary Food and Drug Administration standards for Phase I and II investigations in the United States. Thus the clinical trials with rubidium in this country had to be preceded by

TABLE 1

animal toxicology studies.[1] These results suggested that any study in humans involving doses larger than tracer doses must use oral administration, since rubidium is known to be lethal to animals when it enters the blood stream rapidly. A factor that further complicates clinical trials is that the biological half-life of rubidium is 50 to 60 days; this was determined first by tracer studies and later by our chronic loading studies.

METHOD

A metabolic ward is a prerequisite for studying the metabolism and drug kinetics of any of the alkali metals, such as rubidium. In addition, if the ward is located in a psychiatric hospital, concomitant measurements of behavior can be made for later correlations with levels of plasma, urine, cerebrospinal fluid (CSF), or other body substances. The experimental design that we chose for our Phase I pilot trials provided primarily for extensive medical observation and human safety. It also provided for the determination of the rate of entry of rubidium into the bloodstream and the subsequent urinary excretion rate, as well as recording concomitant behavioral measurements.

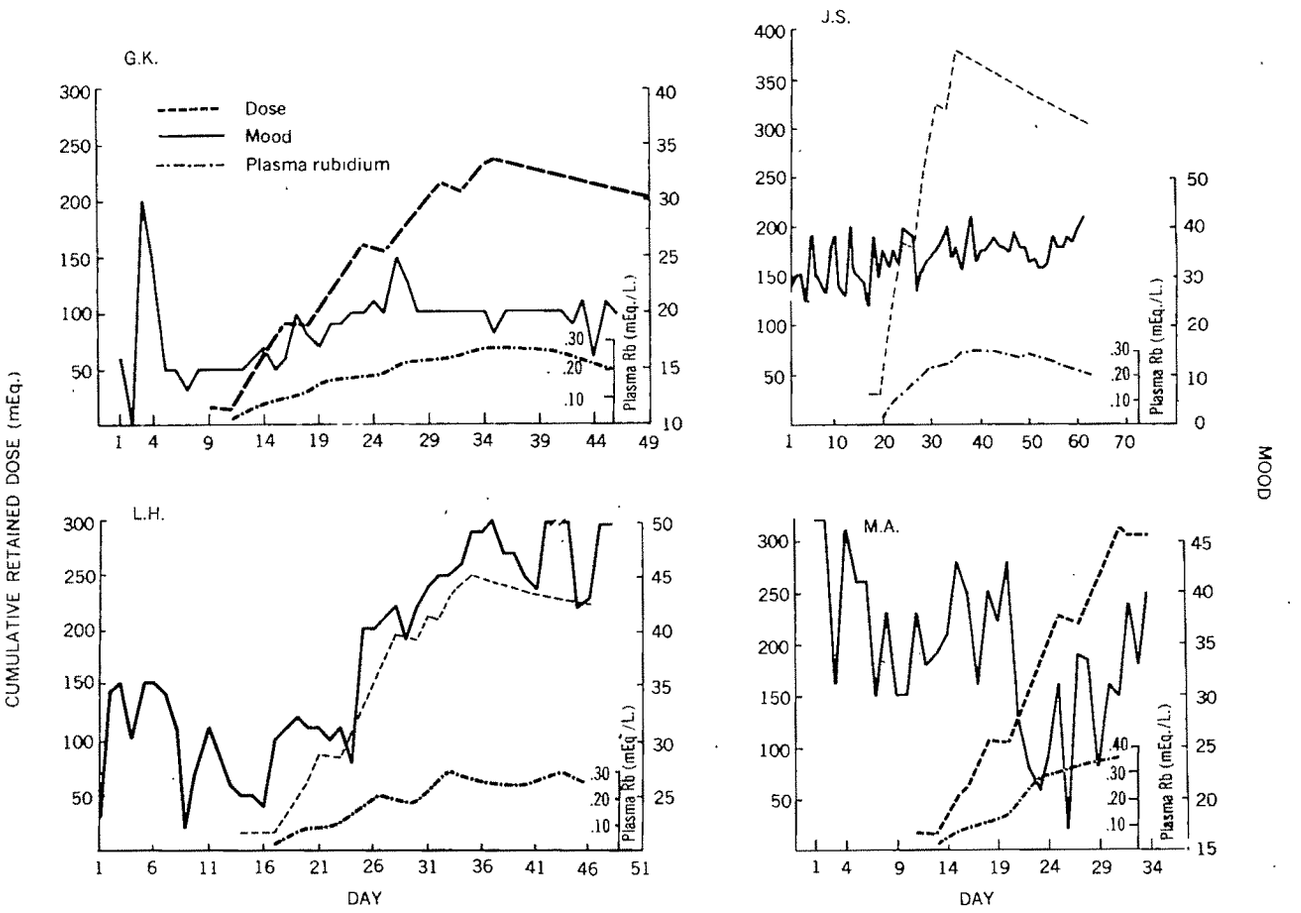
Part I of the study consisted of acute loading experiments, with intensive laboratory observations and observations of affective state being made on four subjects for a period of 24 to 48 hours following oral doses of rubidium chloride.

Part II of the study began with the intensive investigation of one unipolar and four bipolar patients over an extended period of time, during which the plasma rubidium concentration was slowly and safely elevated under conditions of controlled metabolic balance (a daily intake of 5 gm. of sodium plus 60–80 mEq. of potassium).

All subjects were volunteers—two normal subjects and seven depressed patients hospitalized in the Metabolic Research Unit at the New York State Psychiatric Institute. All subjects were free of complicating medical conditions, as determined by medical and neurological examination, blood chemistry, X ray, EEG, and EKG. Particular attention was directed toward the EKG, since rubidium is known to have an effect similar to that of potassium on heart physiology.

Prior to and subsequent to the ingestion of 1–1.5 gm. of rubidium within a four-hour interval, each subject in the acute study was monitored by continual EEG recording, frequent pulse and blood pressure measurements, tests of motor reflexes, EKGs, and observation of the clinical state, as well as collection of blood and 24-hour urine samples for electrolytes. Once the acute studies were successfully performed and safely completed, a series of one unipolar and four bipolar depressive patients were studied with chronic rubidium loading. In the chronic studies, patients were given oral rubidium chloride intermittently for 15 to 86 days, until an estimated cumulative total of no more than 370 mEq. of rubidium was retained. During all placebo and rubidium conditions, patients were rated on several behavioral inventories,[2] including a ten-point manic-depressive rating scale used by trained nurses, who were blind to the medications.

RESULTS



Acute Loading Studies

Table 1 shows that the peak plasma level of rubidium ranged between .014 and .041 mEq./liter per 8.2 mEq. ingested following acute doses of 0.5–1.0 gm. of rubidium chloride. These four subjects showed a minimal to moderate increase in the proportion of the lower frequencies of the EEG and no other changes, objective or subjective, in the acute study. The rubidium content of the urine of the normal subjects in these acute studies (the first two

[1] A bibliography listing these studies is available from the authors on request.

[2] Further information on these unpublished rating scales is available from the authors.

FIGURE 1
Chronic Rubidium Loading in Four Bipolar Depressed Patients

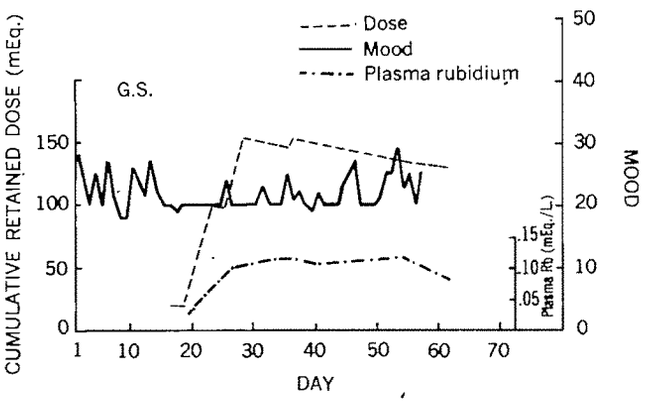
subjects in the table) during the second 12 hours of the 24-hour period was consistent with a biological half-life of 50 to 60 days (see table 1).

Chronic Loading Studies

Figures 1 and 2 illustrate the behavioral and metabolic data collected on unipolar and bipolar depressed patients who have been chronically loaded with rubidium chloride. As can be seen from the figures, the maximum plasma level obtained reached .30 mEq./liter (in patient J.S.; see figure 1) and the maximum cumulative rubidium chloride retained by this patient reached 370 mEq. No immediate or long-term side effects were encountered in any of these five chronically loaded patients and no consistent behavioral or affective changes were recorded at this preliminary dose range. Patient L.H. (see figure 1) came out of her depression during the rubidium trial, and patient J.S. reported subjectively feeling much better, although the behavioral scores obtained by the nurses did not clearly corroborate this. J.S. became seriously depressed and paranoid three weeks after the rubidium chloride was discontinued. Two other patients also appeared to have a depressive rebound three to four weeks after resubstitution of placebo. All patients have now been followed for from six to 18 months subsequent to their chronic loading trial without any reported adverse effects.

General Laboratory Data

All EKG tracings, liver function tests, electrolyte levels, blood urea nitrogen tests, complete blood counts, and urinalyses were consistently normal for the five patients loaded chronically.



CSF Data

Figure 3 illustrates recent data comparing the rubidium content of CSF and blood plasma. Samples were taken at the indicated intervals after the last dose of rubidium chloride. The rubidium content of the blood plasma declined steadily, with an apparent half-life of about 34 days. In contrast, there was a transient increase in the CSF rubidium concentration, followed by a decrease, with a calculated half-life of 37 days.

Related Biochemical Data

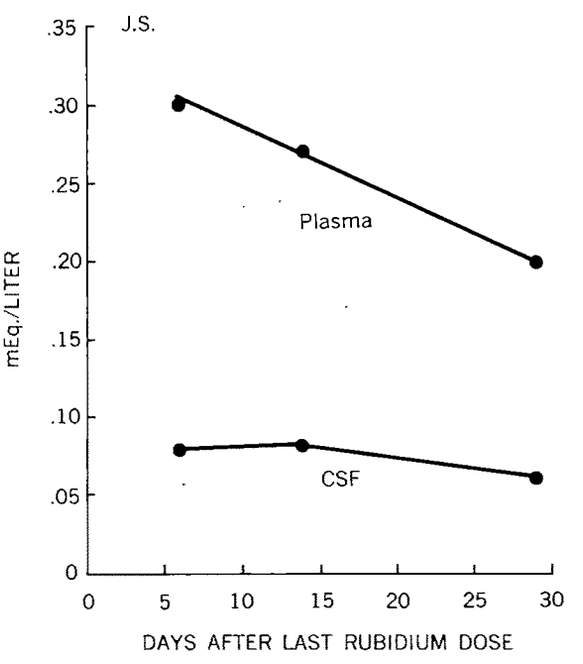
Preliminary data on the biogenic amine metabolites in urine were also accumulated for patients J.S. and M.A. during a pre-rubidium placebo period, during the two

FIGURE 2
Chronic Rubidium Loading in a Unipolar Depressed Patient

weeks of rubidium loading, and during a two-week post-rubidium placebo interval. Free catecholamines, total o-methylated metabolites, and 3-methoxy, 4-hydroxymandelic acid (VMA) were measured in the urine of these two patients by the methods described by Crout (22) and Pisano (23, 24). There were no significant changes noted in the excretion pattern of these metabolites in the patients studied. These preliminary data suggest that rubidium treatment at the dose level employed does not modify the excretion pattern of these urinary biogenic amine metabolites. Urinary studies of 3-methoxy, 4-hydroxyphenylglycol (MHPG) are still in progress.

Preliminary studies of total body potassium (employing K^{40}) were also performed on a single patient (J.S.). These results tended to confirm the animal data of Relman and associates (20) that total body potassium is replaced by rubidium approximately mEq. for mEq. when the latter is ingested orally.

DISCUSSION



Rarely does one have an opportunity to begin a clinical trial of a potentially useful new psychoactive drug with the amount of information from the basic sciences that is available for rubidium. The results of EEG, biogenic amine, and behavioral testing of animals all point to an alerting or arousal effect, as well as aggression-inducing properties in animal paradigms. Rubidium studies performed in four independent laboratories (New York State Psychiatric Institute, Stanford University, University of Melbourne, and NIMH) produced agreement that rubidium exerts neurochemical and behavioral effects "opposite" to those of lithium, a proven and specific antimanic agent. Lithium produces a transient sodium, potassium, and water diuresis in both animal and human subjects and simultaneously corrects states of manic elation in humans. Lithium's effects on unipolar and bipolar depression, in contrast, have generally been much less impressive, thus prompting the continued search for a substance with specific antidepressant properties.

Most psychopharmacologists agree that the classic tricyclic and monoamine oxidase inhibiting agents are superior to placebo but not dramatically so. Furthermore, the onset of action of these drugs often appears to be delayed for ten days to several weeks and their side effects may be quite prominent. One can hypothesize that rubidium, if its use is therapeutic in depression, might offer the possibility of a "replacement-like" therapy for an as-yet-undiscovered biochemical defect or defects in one or more of the depressive subtypes, in the way that lithium appears to offer a specific "replacement-like" therapy for mania.

The significance of rubidium in basic pharmacology, behavioral pharmacology, and electrolyte physiology thus seems to be promising, due to its unique neurochemical and behavioral properties. Its application to clinical psychiatry and/or internal medicine is much less certain, but the potential of rubidium as a research tool or as a possible therapy in states of altered ionic balance in medicine or psychiatry now seems worth exploring.

Of foremost importance in the exploratory results reported in this initial trial with humans is the finding that the rubidium ion can be administered chronically to humans without evidence of toxicity. Furthermore, by means of balance techniques, accurate bookkeeping can be accomplished, so that a gain or loss of major or minor ions can be recognized. The monitoring of these ions, as well as behavior, allows one to conduct studies similar to the metabolic studies that have generated a plethora of research with the lithium ion. Interpretation of the preliminary data presented beyond this point must be made

FIGURE 3
Comparison of the Rubidium Content of Cerebrospinal Fluid and Blood Plasma

with extreme caution. Of the five patients chronically loaded with rubidium, a single patient clearly recovered from her depressive episode during the trial, while a second patient rated himself subjectively better during the latter phases of the rubidium loading, only to become psychotically depressed three weeks later after discontinuance of the ion when placebo was resubstituted. In the other three patients who were loaded chronically, there was no correlation between change in depressive affect or behavior and the rubidium loading, although the clinical course of two of these patients worsened three to six weeks after placebo resubstitution.

Preliminary findings with respect to the rubidium content of cerebrospinal fluid are of interest. The simplest explanation for the contrasting values obtained for CSF and plasma rubidium is based on the reasonable assumption that CSF represents the extracellular fluid of brain and that the higher rubidium concentration in the second CSF sample probably represents the continued accumulation of rubidium by brain. Although this interpretation must be regarded as preliminary, it should be noted that this is consistent with our animal data (not yet published), which shows that Rb^{86} continues to accumulate in rat brain, reaching a maximum at three days after injection, while the peak level occurs after one day in all other organs studied.

No conclusions can be made with respect to the preliminary biogenic amine studies undertaken in this report. In addition to the fact that the usual difficulties in interpretation of urinary amine data apply to the two patients (J.S. and M.A.) who were studied, it should also be noted that these negative results may have been due to the use of a dose level too far below the yet unknown level at which a therapeutic result may occur. We are now planning studies with depressed patients that will use a higher level of plasma rubidium and total cumulative rubidium intake; during these studies CSF and urinary amine metabolites, including MHPG, will also be analyzed. The decision to investigate amine metabolites and rubidium was prompted by the rubidium-induced biogenic amine changes in animal studies noted by Stolk and associates (13) and Eichelman and associates (19), referred to previously, as well as the urinary amine studies in humans reported by Greenspan and associates (25), which correlated lithium treatment, decreasing manic behavior, and changes in urinary VMA, normetanephrine, and MHPG.

The design of an experimental trial of a drug, such as rubidium, that has a long biological half-life (50 to 60 days) presents unique legal, ethical, and safety problems not heretofore encountered in clinical psychopharmacology, as well as special problems in the interpretation of results. The therapeutic effect of rubidium in a depressed patient can only be assessed by cautious stepwise increments in the plasma level and the total cumulative retained dose, with pauses that permit each new level to be correlated with clinical improvement and/or physiological or subjective side effects. A sufficiently large number of metabolic and behavioral observations at increasing doses of rubidium with single cases will be necessary to obtain the basic data required in Phase I and II clinical trials with this ion. Such raw phenomenological data will provide the basic data needed to establish the drug's effectiveness, ineffectiveness, and/or toxicity and tolerance levels in that illness. Should higher doses or more prolonged oral doses of rubidium result in a positive correlation between increased serum rubidium levels and decreasing depression scores, the hypothesis of therapeutic efficacy then becomes worth testing in a Phase III double-blind study with randomization of a sufficiently large number of patients to drug and placebo.

In conclusion, an extensive and exciting field of electrolyte metabolism in medicine and psychiatry still remains unexplored. In addition to future studies with rubidium, a number of other trace metal ions await exploration in basic and clinical psychopharmacology.

Amphetamine Psychosis: A "Model" Schizophrenia Mediated by Catecholamines

BY SOLOMON H. SNYDER, M.D.

Because of its close clinical similarity to acute paranoid schizophrenia, amphetamine psychosis may serve as a useful experimental model for schizophrenia. Molecular and clinical studies suggest that both the schizophrenia-like symptoms of amphetamine psychosis and the specific ability of phenothiazines to relieve the symptoms of schizophrenia and amphetamine psychosis may be the result of interactions with dopamine systems in the brain. The author discusses some implications of the roles dopamine and norepinephrine may play in mediating some schizophrenic symptoms.

PSYCHIATRISTS HAVE for years sought an experimental, preferably drug-induced, "model schizophrenia." Many drugs elicit psychoses, but most are considered toxic, because the psychotic thinking is accompanied by confusion and disorientation.

Amphetamine psychosis has been suggested as a model for paranoid schizophrenia (1, 2). The simplest argument in its favor is that numerous patients with amphetamine psychosis have been misdiagnosed and mistreated, often for long periods, as paranoid schizophrenics (1–3). Another obvious similarity between amphetamine psychosis and certain forms of schizophrenia is the similarity in drug therapy. Phenothiazines, which have selective antischizophrenic activity (4), are also uniquely efficacious antidotes for amphetamine poisoning (5) and psychosis (6).

Because of the obvious chemical similarities, amphetamines have usually been assumed to exert most of their behavioral effects through interactions with one or the other of the brain catecholamines norepinephrine and dopamine. An abundance of recent research has enabled pharmacologists to ascribe specific behavioral effects of amphetamine to its effects on neuronal stores of the catecholamines and of phenothiazines to their actions on catecholamine receptors in the brain.

I will attempt to contrast the clinical features of amphetamine psychosis with particular forms of schizophrenia, to review the pathways of norepinephrine and dopamine neuronal tracts and their selective interactions with amphetamine and phenothiazines, and finally to point toward the possible relationships between some features of amphetamine psychosis and interactions of the drug with catecholamines.

CLINICAL FEATURES OF AMPHETAMINE PSYCHOSIS

There is little doubt that amphetamine psychosis can closely mimic paranoid schizophrenia. Beamish and Kiloh (3) provided detailed case histories of patients with amphetamine psychosis in which a misdiagnosis of paranoid schizophrenia was maintained for up to three years, during which time patients received courses of electroconvulsive shock and insulin coma therapy, all the while surreptitiously ingesting amphetamine in the hospital. Bell (2) described 14 cases of amphetamine psychosis, seven of which were first diagnosed as paranoid schizophrenia. Some authors, however, feel that certain differences permit differential diagnoses of these two conditions solely on clinical grounds (2, 7).

What are the major symptoms of amphetamine psy-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Snyder is Professor of Psychiatry and Pharmacology, Johns Hopkins University School of Medicine, Baltimore, Md. 21205.

chosis? Paranoid ideation, along with well-formed delusions, is a hallmark (1, 8). Delusions begin with a vague suspiciousness, followed by increasing ideas of reference. In studies of experimentally induced amphetamine psychosis, the psychosis proper began abruptly when the patients crystallized their heretofore vague apprehensions into fixed paranoid delusional systems (9, 10). Characteristic behavioral effects of amphetamine that may contribute to paranoid features of the psychosis include heightened awareness, an acute sense of novelty and curiosity, and the overwhelming fear and terror often displayed by heavy users of amphetamines (8).

A recently emphasized symptom of amphetamine addicts and psychotics is stereotyped compulsive behavior. Patients compulsively take objects apart, sort them, and put them back together again. They analyze details in a concrete and repetitious manner. Often patients pace back and forth and move their mouths from side to side in a stereotyped grimacing pattern. Stereotyped compulsive behavior may be an invariable concomitant of psychosis, present only in those amphetamine addicts who develop psychosis (8).

A majority of patients with amphetamine psychosis experience visual and auditory hallucinations with a similar incidence (1–3, 8–10). The auditory hallucinations are very much like typical schizophrenic auditory hallucinations, with vague noises, voices, and occasional conversations with the voices (1, 2). This contrasts with the psychotomimetic effects of psychedelic drugs, which primarily elicit visual distortions. Still, the occurrence of a significant proportion of visual hallucinations in amphetamine psychosis can be construed as a feature distinguishing it from schizophrenia, since schizophrenic hallucinations are usually auditory (2, 7). On the other hand, visual hallucinations may be frequent in acute schizophrenics (11, 12), and visual hallucinations in amphetamine psychotics occur primarily in those who become psychotic acutely, often after a single large dose, while auditory hallucinations preponderate in patients whose illness developed gradually with chronic dosage (1).

Tactile and olfactory hallucinations occur frequently in amphetamine psychotics but rarely in schizophrenics. Tactile hallucinations often develop into delusional systems of small animals, worms or lice, or crystals of amphetamine that have been placed beneath the patient's skin.

Most amphetamine addicts report a change in sexual habits, with decreased sexuality in some patients, but more frequent and more striking alterations occur in the direction of sexual excess and perversities. Ellinwood (8) reported that sexual stimulation is associated selectively with patients who become psychotic. From his studies of Swedish phenmetrazine hydrochloride (Preludin) addicts, Rylander concluded that amphetamines are the most powerful aphrodisiacs known (13).

A key feature of amphetamine psychosis is the retention of clear consciousness and correct orientation. Indeed, most patients have a hyperacute memory for all events that transpire during their intoxication. It is also of importance that amphetamine psychosis is induced by the drug itself rather than by its withdrawal; symptoms abate as the drug is excreted (14).

Certain clinical features are conspicuous by their absence in amphetamine psychosis. Few patients display a formal thought disorder, a feature proposed as differentiating this condition from paranoid schizophrenia (2, 7, 15). Unlike most schizophrenics, patients with amphetamine psychosis also often manifest not a flat affect but rather a "brisk emotional reaction, usually in the direction of anxiety" (7).

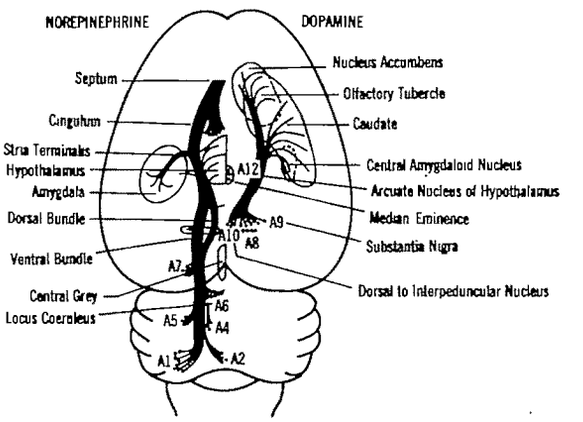
Because amphetamine psychosis usually occurs in chronic heavy users of the drug, one may ask whether the psychosis is an effect of the drug or is merely secondary to sleep deprivation, "overstimulation," or precipitation of a latent schizophrenia. The experimental induction of amphetamine psychosis in volunteer human subjects has resolved some of these issues (9, 10). Griffith and associates (9) administered amphetamine at a rate of 10 mg. per hour by mouth every hour to four subjects, all of whom sustained an unequivocal psychosis between two and five days after the start of the experiment. The experimenters excluded from their study anyone with a prior history of amphetamine psychosis or schizoid or schizophrenic tendencies. Their ability to reproducibly induce a psychotic state therefore suggests that amphetamine psychosis is not simply a drug-activated latent schizophrenia. Two of the subjects became psychotic on the second day, at which time amphetamine administration was terminated, so that they lost only one night of sleep. This is too short a period of sleep deprivation to elicit psychosis, indicating that amphetamine psychosis is not attributable simply to sleep deprivation. Because the subjects in the study were depressed rather than stimulated after the first few hours of the experiment, the psychosis probably was not a product of "hyperarousal," although observable activity may fail to reflect internal hyperarousal.

In summary, patients receiving large doses of amphetamine frequently develop a psychosis that resembles paranoid schizophrenia. The clinical picture, however, differs in a number of ways from that of schizophrenia. Perhaps the differences are attributable to other "contaminating" amphetamine effects, such as central stimulation along with sleeplessness, anorexia, and sexual stimulation.

Recently, particular behavioral effects of amphetamines and phenothiazines have been linked to specific neurochemical systems. Such findings may help to clarify the pathophysiology of amphetamine psychosis.

NOREPINEPHRINE AND DOPAMINE PATHWAYS IN THE BRAIN

In searching for the biochemical mechanisms of amphetamine action, pharmacologists have a head start over research on most other drugs. Since amphetamine bears so close a chemical resemblance to norepinephrine and dopamine, most investigators attribute the behavioral ac-



tions of amphetamine to one or the other of these two chemicals.

While amphetamine can interact with catecholamines in a variety of ways, most pharmacologists currently favor two mechanisms: a direct synaptic release and inhibition of reuptake inactivation (16). Reuptake inactivation refers to a process whereby synaptically released catecholamines are inactivated primarily by reuptake into the nerve endings that had released them. In either case, amphetamine potentiates catecholamine effects.

A major advance in understanding brain catecholamines was the development of a histochemical fluorescent technique whereby dopamine and norepinephrine could be detected and distinguished from each other in specific neurons in freeze-dried sections of the brain (17). The neuronal pathways containing these amines have been most recently and thoroughly mapped by Ungerstedt (18); see figure 1.

FIGURE 1

*Pathways of the Norepinephrine and Dopamine Tracts in Rat Brain**

*Adapted from Ungerstedt (18).

Norepinephrine Pathways

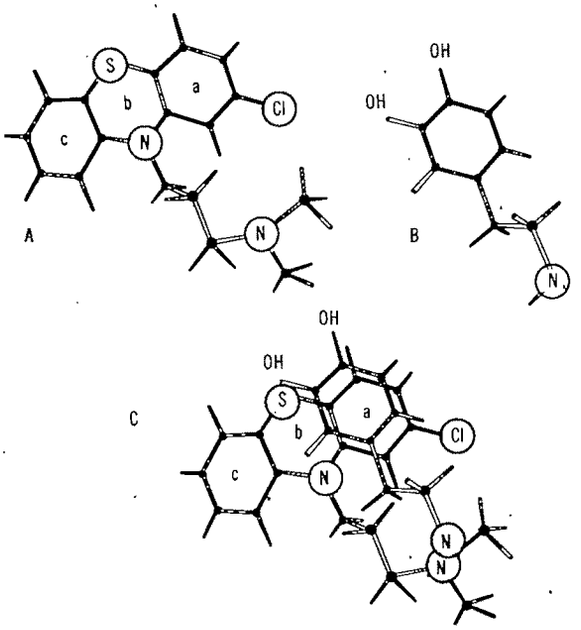
Ventral norepinephrine system. The cell bodies of this system occur in about four different groupings in the medulla oblongata-pons. Their axons ascend in the medial forebrain bundle, giving off terminals first in the lower brain stem, then in the midbrain, and finally in large numbers throughout the hypothalamus.

Dorsal norepinephrine system. The other major norepinephrine tracts have cell bodies in the locus coeruleus. Some fibers proceed downward to innervate lower brain stem areas, here overlapping with nerve terminals of the ventral norepinephrine pathway. A larger proportion, however, send ascending axons more dorsally than the ventral norepinephrine pathway (hence the "dorsal norepinephrine pathway") to innervate the entire cerebral cortex and hippocampus. Some axons, after leaving the locus coeruleus, enter the cerebellum. Interestingly, axons arising from single cells of the locus coeruleus may divide and send separate branches to the cerebral cortex, the hippocampus, and the cerebellar cortex. Thus a single neuron can influence these widely separated areas of the brain.

Dopamine Pathways

Nigrostriatal dopamine system. The best known dopamine tract has cell bodies in the midbrain's substantia nigra with axons ascending to terminate in the caudate nucleus and putamen of the corpus striatum. The nigrostriatal system is degenerated in the brains of patients with Parkinson's disease; the attendent dopamine deficiency appears to account for many parkinsonian symptoms (19).

The meso-limbic dopamine system. Dopamine cell bodies near the interpeduncular nucleus in the midbrain ascend along with axons of the nigrostriatal dopamine system but diverge to give off terminals in the nucleus accumbens and the olfactory tubercle, two poorly understood parts of the brain.



The tubero-infundibular dopamine system. Some dopamine cell bodies, located in the arcuate nucleus of the hypothalamus, send forth short axons that terminate in the median eminence. Impressive evidence implicates this dopamine tract in the regulation of secretion and synthesis of the trophic hormones of the pituitary gland (20).

Simply by knowing the course of the various catecholamine tracts one may make well-educated guesses as to which ones mediate particular behavioral effects of amphetamine. For instance, the medial forebrain bundle is well known as a "reward center" of the brain (21). Animals will press levers at astronomical rates just to obtain electrical stimulation in the medial forebrain bundle. Amphetamine greatly facilitates self-stimulation in the medial forebrain bundle (22). Since the ventral norepinephrine pathway accounts for the majority of catecholamine axons and terminals in the area of the medial forebrain bundle, it would be reasonable to suppose that amphetamine's effects on this tract account for the euphoriant, and conceivably the sexual stimulant, actions of the drug. The medial forebrain bundle's norepinephrine neurons may be responsible for self-stimulating behavior, since blocking the conversion of dopamine to norepinephrine inhibits self-stimulation there and since the suppressed behavior can be reinstated by intraventricular injections of norepinephrine (23).

Influences of the brain stem on the cerebral cortex are probably responsible for maintaining a state of alertness. Some years ago Bradley and Elkes (24) showed that the alerting effects of amphetamine are mediated by influences from the brain stem's reticular formation on cerebral arousal mechanisms. Perhaps the responsible site in the brain stem is the locus coeruleus and its fibers, by which norepinephrine ascends to the cerebral cortex. Conceivably, the norepinephrine fibers to the cerebellum account for the enhancement by amphetamine of motor coordination. Since alertness and muscle coordination are mutually interdependent processes, their interrelation might be subserved by the neuronal architecture whereby single norepinephrine neurons in the locus coeruleus pro-

*Structural Similarity of Chlorpromazine and Dopamine**

*Drawings are Dreiding models of the molecular structures of chlorpromazine (A) and dopamine (B), as determined by X-ray crystallographic analysis; part C illustrates how dopamine may be superimposed on a portion of the chlorpromazine molecule.

ject both to the cerebrum and to the cerebellum.

The therapeutic efficacy of L-dopa in Parkinson's disease appears to depend largely on its decarboxylation to dopamine, which ameliorates the dopamine deficiency in the brains of these patients (25–27). Dextroamphetamine has been employed as an effective therapeutic agent in Parkinson's disease (28, 29). It may act by potentiating the limited amounts of dopamine remaining in the brains of parkinsonian patients.

The functions of the meso-limbic dopamine system are obscure. One might hypothesize that the meso-limbic terminals in the olfactory tubercle play a part in the olfactory hallucinations that frequently occur in amphetamine psychosis.

INTERACTION OF PHENOTHIAZINES WITH DOPAMINE RECEPTORS

Just as the obvious chemical similarities of amphetamines and catecholamines portended their pharmacologic relationships, recent findings of a more subtle resemblance of catecholamines and phenothiazines (30) may explicate certain therapeutic effects of the phenothiazines. In this case the pharmacologic data preceded the chemical observations.

It has already been mentioned that the phenothiazines, which are selectively antischizophrenic, are also potent antidotes to amphetamine psychosis. Phenothiazines alter dopamine metabolism in a fashion that suggests that they block dopamine receptors in the brain (31–33). Although phenothiazines can also block apparent norepinephrine receptors, their potency in blocking dopamine receptors is much greater than their norepinephrine-blocking capacity (31–33). Because the antipsychotic and dopamine-blocking potencies of phenothiazines are closely correlated, it has been suggested that the antischizophrenic activity of these drugs is related to the blockade of dopamine receptors at one or another of the dopamine tracts in the brain (34, 35).

Horn and Snyder (30) recently observed a close similarity between the preferred conformations of chlorpromazine and dopamine, as determined by X-ray analysis (figure 2), which indicates a possible molecular mechanism by which phenothiazines block dopamine receptors and which accounts in part for several clinical features of phenothiazine action.

The similarity of the dopamine conformation to part of the chlorpromazine structure accords with the possibility that phenothiazines may exert their clinical effects by interacting with dopamine-related sites. If this is so, the ability of phenothiazine drugs to assume the dopamine-like conformation should be related to their antischizophrenic activity, a prediction borne out in analysis of molecular models (30). For instance, a substituent at position 2 of the *a* ring of phenothiazines is crucial for antischizophrenic activity (36). Without an *a* ring substituent, rings *a* and *c* would be almost symmetrical, with the side chain presumably fully extended, and the resultant compound would therefore be less likely to assume the dopamine-like conformation. If antischizophrenic activity is determined by the blockade of dopamine receptors, one would then predict that phenothiazines lacking the *a* ring substituent would be less effective antischizophrenic agents. Of all the phenothiazines widely used in treating schizophrenia, only promazine and mepazine lack the *a* ring substituents, and these two agents are significantly less clinically efficacious than those that do contain an *a* ring substituent.

Another major requirement for the antischizophrenic activity of phenothiazines is that the side chain amine group be separated by three carbon atoms from the ring system. Molecular models indicated that shortening the side chain to two carbon atoms would make the assumption of the dopamine-like conformation less likely (30). Accordingly, it is of interest that phenothiazines with side chains of two carbon atoms, such as the antihistamine promethazine (Phenergan) and the antiparkinsonian agent diethazine (Diparcol), appear to lack antischizophrenic activity (36). Other features of antischizophrenic activity of phenothiazine drugs explained by the resemblance to the conformation of dopamine (30) will not be described here.

BEHAVIORAL EFFECTS OF AMPHETAMINE IN ANIMALS

Resolving the multifarious actions of amphetamine requires knowing which of the catecholamines, and ulti-

mately which specific tract in the brain, accounts for each effect. In our laboratory the pharmacologic artifice of comparing d- and l-isomers of amphetamine has facilitated drawing some of these distinctions. D-amphetamine is ten times as potent as l-amphetamine in blocking the reuptake of catecholamines by norepinephrine neurons but is about equal to l-amphetamine in acting on dopamine neurons (37–40). The same relative potencies of the amphetamine isomers also appear to hold for the amphetamine-elicited release of norepinephrine and dopamine (39, 41). Thus for the two major modes of amphetamine action—inhibition of reuptake inactivation and synaptic release—d-amphetamine is considerably more potent than l-amphetamine in affecting norepinephrine neurons, while the two isomers have similar potencies in affecting dopamine neurons.

Assuming that these biochemical actions are responsible for the behavioral effects of amphetamine, there emerges a simple way to determine whether a particular animal or human behavior involves brain dopamine or norepinephrine: if d-amphetamine is much more potent than l-amphetamine in eliciting the behavior, norepinephrine can be held responsible, but if d- and l-amphetamine show similar behavioral potencies, dopamine is implicated as the transmitter.

Earlier studies have reported comparisons of the two amphetamine isomers in evoking two behavioral effects of amphetamine in animals—locomotor stimulation and stereotyped behavior (38–40). At relatively low amphetamine doses, animals appear excited and will run around their cages at a furious rate, an effect that may mirror the central stimulant actions of amphetamine in man. D-amphetamine was ten times as potent as l-amphetamine in enhancing locomotor activity in rats, paralleling the ten-fold difference between these isomers in inhibiting the reuptake of catecholamines by norepinephrine neurons. This suggests that amphetamine-induced locomotor stimulation in animals, and possibly central stimulation in man, involves brain norepinephrine. Drugs that block the conversion of dopamine to norepinephrine diminish the locomotor stimulant actions of amphetamine, which also suggests that norepinephrine rather than dopamine mediates this behavior (42).

At somewhat higher doses, amphetamine elicits stereotyped compulsive behavior in animals, the exact pattern varying with different species. In rats, whose major means of exploring their environment is olfactory, animals stay in one portion of the cage, sniff, lick, and gnaw. Motoric components of this behavior resemble the involuntary movements elicited in parkinsonian patients by large doses of L-dopa, as well as the motor tics of Gilles de la Tourette's disease (40).

In cats and monkeys, the stereotyped behavior produced by amphetamine takes on a "searching" quality. Chimpanzees intoxicated with amphetamine display patterns of looking from side to side, as well as self-picking and grooming behavior, that are reminiscent of the stereotyped purposeless searching and grooming behavior of human amphetamine addicts (43). Ellinwood, who has studied human amphetamine psychosis as well as the effects of chronic amphetamine administration in rats, cats, and monkeys, has emphasized the formal similarities of the human and animal stereotyped behaviors (44).

We found d-amphetamine only twice as potent as the l-isomer in eliciting stereotyped behavior in rats, which is much less than the ten-fold difference in the capacity of these drugs to stimulate locomotor activity (38–40), thus implicating dopamine as the catecholamine of major importance in mediating this behavior. The fact that the two isomers were not quite equal in activity suggests that norepinephrine may play some role, conceivably a triggering one, in the stereotyped behavior.

Other evidence also implicates dopamine in the stereotyped behavior. While drugs that block the conversion of dopamine to norepinephrine diminish amphetamine-induced locomotor stimulation, they fail to alter the stereotyped compulsive behavior (42, 45). Although large lesions in the corpus striatum abolish the stereotyped behavioral effects of amphetamine (46), experiments with more discrete lesions implicate the olfactory tubercle (47) and the nucleus accumbens (48) as the specific dopamine tracts responsible for certain components of the stereotyped behavioral syndrome.

If the stereotyped behavior of amphetamine psychotics is analogous to the similar behavior elicited by amphetamine in animals, then the evidence for dopaminergic mediation of these effects in animals might apply also to man. However, it is not clear whether stereotyped compulsive behavior is a primary feature of amphetamine psychosis itself. The most dramatic and schizophrenic-like aspect of amphetamine psychosis is paranoid thinking.

On the basis of animal studies comparing d- and l-amphetamine, Angrist and associates (49) deduced that comparing in humans the potencies of d- and l-amphetamine in eliciting amphetamine psychosis might indicate the relative roles of dopamine and norepinephrine. Accordingly, three volunteers were given escalating doses of d- or l-amphetamine on separate occasions. All three subjects were rendered psychotic by the drug. Strikingly, d-amphetamine and l-amphetamine had similar potencies in eliciting the psychosis. In the three patients, the ratios of the total doses of l-amphetamine to d-amphetamine required to produce the psychosis were 1.25, 1.53, and 1.0.

How do these data compare with the relative potencies of these isomers in eliciting central stimulation in man? D-amphetamine is about four times as potent as l-amphetamine as a central stimulant in man (50). Angrist and associates (49) observed that, during the early stages of amphetamine administration, considerably greater stimulant effects were observed with d-amphetamine than with l-amphetamine. These symptoms included jitteriness, talkativeness, increased motor activity, and a generally enhanced alertness. With comparable doses, l-amphetamine produced few if any of these effects. Thus, in human subjects, d- and l-amphetamine were much more similar in their capacity to elicit psychosis than in their ability to effect central stimulation.

Assuming that the comparative neurochemistry of

dopamine and norepinephrine neurons is similar in man to that in animals, one might conclude from this experiment that the induction of amphetamine psychosis is mediated by one or another dopamine tract in the brain.

CONCLUSIONS

Returning to the possible role of amphetamine psychosis as a model of schizophrenia, one difficulty already mentioned is that the amphetamine illness selectively resembles paranoid schizophrenia. Besides its psychotogenic effects, amphetamine produces a wide spectrum of other effects. Perhaps if amphetamine acted solely on selected dopamine tracts, the psychosis it precipitates would be a more faithful model of an undifferentiated form of schizophrenia or one whose characteristics were determined primarily by the patient's previous personality. Conceivably other amphetamine effects transform the model schizophrenia into a predominantly paranoid psychosis.

One possible candidate for a contaminating action would be the norepinephrine-mediated alerting effect of amphetamine. One might speculate that this alerting action forces the patient to strive for an intellectual framework in which to focus all the strange feelings that are coming over him as the psychosis develops. This quest for meaning and its subsequent "discovery" in a system of delusions might be the essence of the paranoid process in these patients. According to this reasoning, a schizophrenia-like component of amphetamine psychosis might be mediated primarily by brain dopamine while the "paranoid solution" is facilitated by the drug's alerting effects through the stimulation of the norepinephrine systems.

If indeed the norepinephrine-mediated alerting actions of amphetamine interact with and contaminate a purer, dopamine-mediated amphetamine psychosis, then removal of these "norepinephrine effects" might leave one with an amphetamine psychosis more closely resembling schizophrenia than the present version. Drugs that would stimulate dopamine mechanisms but not norepinephrine mechanisms in the brain might elicit such a "pure" model of schizophrenia.

Psychomotor Activity and Cerebrospinal Fluid Amine Metabolites in Affective Illness

BY ROBERT M. POST, M.D., JOEL KOTIN, M.D., FREDERICK K. GOODWIN, M.D., AND EDNA K. GORDON

In order to evaluate the effect of psychomotor activity on CSF amine metabolites, lumbar punctures were performed after moderately depressed patients had simulated manic hyperactivity for four hours. The CSF levels of 5-hydroxyindoleacetic acid (5-HIAA) and homovanillic acid (HVA) were significantly higher after simulated mania or exercise alone than in the same patients after bed rest. In addition, there was a trend for levels of 3-methoxy-4-hydroxyphenylglycol to increase with activity. The levels of 5-HIAA and HVA correlated with the amount of motor activity: lowest in depression, intermediate in mania and hypomania, and highest in simulated mania. Both metabolites were higher in severe mania than in hypomania. These results suggest that psychomotor activity is an important determinant of CSF amine metabolite levels in affective illness.

THIS STUDY was designed to evaluate systematically the effect of psychomotor activity on amine metabolites in the cerebrospinal fluid of patients with affective illness.

It has been suggested, largely on the basis of indirect pharmacological evidence, that alterations in brain neurotransmitter amines (norepinephrine, dopamine, and serotonin) may be involved in the pathophysiology of affective disorders (1–3). A number of investigators have attempted a more direct evaluation of these hypotheses by measuring levels of amine metabolites in the cerebrospinal fluid (CSF) of patients with affective illness. Particular attention has been given to 5-hydroxyindoleacetic acid (5-HIAA), homovanillic acid (HVA), and 3-methoxy-4-hydroxyphenylglycol (MHPG), the major central metabolites of serotonin, dopamine, and norepinephrine, respectively.

Several investigators have reported lower levels of

*The various control groups consisted of neurologic, psychiatric, and alcoholic patients (4); neurologic patients (5,6,9); non-affectively ill patients (7,18); normal volunteers (11,16); nondepressed patients without neurological abnormalities (8); neurological patients without extrapyramidal, epileptic, or senile illness (10,13); normal parents of neurologic patients (13); and schizophrenics (15).
**CSF was taken after one hour of exercise.
***Data are presented as mean±S.E.M.
†The control group cited was studied in collaboration with T.N. Chase; data are presented as mean±S.E.M.
††Subgroup of patients with retarded depression.

CSF 5-HIAA in depressed patients than in neurological controls (4, 5), normal volunteers (6), and non-affectively disturbed controls (7, 8). Others, however, have failed to find significantly lower levels in depression (9–11). The 5-HIAA values in manic patients have been found to be low (6, 7), normal (4, 9), or high (11) in comparison with those of controls. Two groups (4, 6) have found a trend toward higher values of 5-HIAA in mania than in depression.

We have recently reported data on the CSF 5-HIAA levels of a group of 55 depressed patients, 16 hypomanic and manic patients, and 29 controls,[1] all studied under the same conditions at NIMH. The control group was made up of 19 patients with neurological syndromes thought not to involve the central nervous system and ten normal parents of children admitted for neurological evaluation. There were no significant differences in the CSF 5-HIAA between depressed, manic, and control groups (13). These various results from the literature are summarized in table 1.

[1] The control group was studied by T.N. Chase and E.K. Gordon. Some of the data from this group have been published previously (12).

With regard to CSF HVA levels, similar discrepancies exist in the literature. The level of the dopamine metabolite in depressed patients has been reported to be lower than in neurological patients by some authors (10, 11), but not to be different from that in nondepressed psychiatric patients (9) or in an unspecified control group (18) by others. In the few manic patients studied, the HVA values did not vary significantly from those of depressed patients or controls in one study (9), while another group found HVA to be higher in manic than in depressed patients (11, 17).

In our studies, depressed patients had lower HVA levels than did manic patients ($p < .05$) or controls ($p < .10$) (19). The HVA results in the literature are also summarized in table 1.

Studies from this laboratory (20, 21) have indicated that CSF MHPG levels were lower in depressed patients than in manic patients or controls. However, another laboratory has been unable to find any difference between depressed patients and controls, but did report significantly higher levels in manic patients (22).

The present study was designed to evaluate one of the factors that might contribute to the inconsistency and

variability in these reports of CSF amine metabolites—namely, the level of physical or psychomotor activity prior to the sampling of the CSF. The possibility that the degree of activity might affect amine metabolite levels in the CSF was suggested to us by the general trend for amine metabolites to be reported as lower in depression and slightly higher in mania.

To investigate this hypothesis, moderately depressed patients were asked to simulate a state of manic hyperactivity and euphoria and the CSF amine metabolite levels were studied before and after the simulation in each patient. Two additional patients were asked to be only physically active. To our knowledge, the only previous data related to this question were obtained by Fotherby and associates (15), who found slight but nonsignificant increases in CSF 5-HIAA after one hour of exercise in six patients. Van Praag (8) and Papeschi and McClure (10) reported that motor activity in their depressed patients did not correlate with CSF amine metabolite levels, whereas Bowers and associates (9) noted the possibility that physical activity may affect 5-HIAA levels.

METHOD

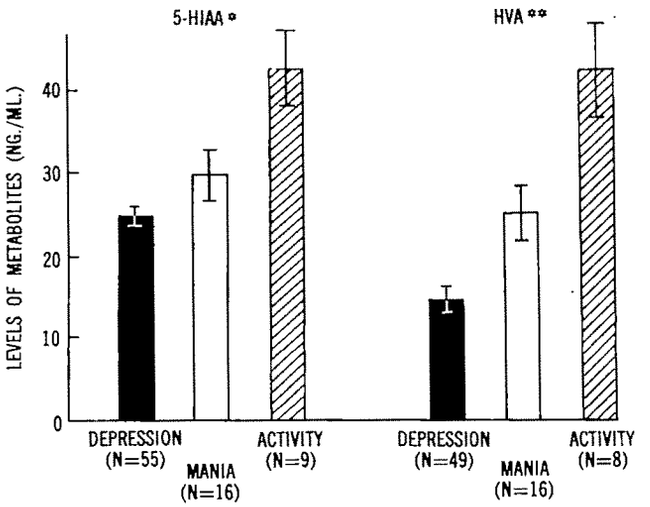
Baseline Studies

Physically healthy patients, screened diagnostically for primary affective illness by two physicians and a social worker, were studied on two 12-bed metabolic research units at the National Institute of Mental Health. The behavior of all patients was rated twice daily by a trained nursing research team, using a multi-item 15-point scale designed for the evaluation of depression and mania (23). Patients were drug-free for two weeks prior to each lumbar puncture (LP) and special care was taken to avoid sedatives, phenothiazines, and salicylates.[2]

[2] Two patients were maintained on constant doses of a drug (one on lithium and one on methadone) during the baseline and hyperactivity LPs.

Only patients who volunteered after a careful explanation of the procedure and its purpose were included. Baseline LPs were performed at 9 a.m., with patients in the lateral decubitus position. The patients fasted and remained at bed rest from midnight until the LP. The first 8 ml. of CSF were collected in 20 mg. of ascorbic acid and immediately frozen at -20C. The 5-HIAA was measured by the method of Ashcroft and Sharman (24), HVA by the method of Gerbode and Bowers (25), and MHPG by the method of Gordon and Oliver (20), involving electron-capture gas-liquid chromatography. In addition, 1 ml. of CSF from these patients was frozen for the determination of levels of cyclic-adenosinemonophosphate (cyclic-AMP) (26).

Simulation of Mania



After the baseline LPs were performed, seven patients, who were moderately depressed but willing to attempt to simulate mania, were awakened at 5 a.m. and, in the company of at least one staff member, remained active for four hours until the repeat LP was performed at 9 a.m. All subjects had observed true manic patients on the ward, so they had little difficulty in finding a model for their behavior. With staff participation and encouragement, these patients were hyperactive and, in most cases, hyperverbal. They ran up and down the corridors; played ping-pong, tennis, and pool; danced, sang, and told jokes; did light calisthenics; drew murals on the walls; and often disrupted the ward in the true spirit of the experimental manipulation.

The 9 a.m. LP after the simulation of mania followed the baseline LP by one day for three patients and by two, 17, 24, and 48 days for each of the other four patients. These patients remained in a similar clinical condition and received similar depression ratings during the interval between the LPs.

Physical Activity

In order to attempt to separate the effects of physical activity from those of increased verbal activity and

FIGURE 1

*The levels of 5-HIAA did not differ significantly between mania and depression, but the levels after activity were higher than those in either depression ($p<.001$) or mania ($p<.02$).
**The levels of HVA were lower in depression than in mania ($p<.05$); the levels after activity were also significantly higher than those in either depression ($p<.001$) or mania ($p<.05$).

heightened mood, two patients were asked to be only physically hyperactive; no attempt was made to imitate mania or a manic mood. The procedure for patient 8 was otherwise identical to that described above, while patient 9 was active from 8 a.m. to 12 noon and received an LP at 3 p.m. This LP was compared with an LP taken at 3 p.m. two days previously, before which the patient was not at bed rest and was allowed his usual moderate activity on the ward.

RESULTS

Success of the Simulated Mania

All of the subjects were able to cooperate with the procedure and were clearly hyperactive from 5 a.m. until the LP was performed at 9 a.m. Most patients experienced some mood elevation during the procedure and regarded the experience as a positive one. Patient 4, who had marked diurnal variation in her depression, reported that she felt better during and after the simulation of mania, in contrast to the usual intensification of her depression in the morning. In the case of patient 1, who had a past history of brief manic episodes, it was virtually impossible to determine whether she was simulating mania or, in fact, had become manic. In other patients it was more readily apparent that they were acting and they reported mixed feelings about their roles.

Amine Metabolites in Simulated Mania and Physical Hyperactivity

The levels of CSF amine metabolites following the simulation of mania were higher than those obtained from the same patients while at bed rest (see table 2). In the two patients who were only physically hyperactive, the increased levels of amine metabolites were of the same order of magnitude as those of patients who simulated mania. If the baseline and hyperactivity LPs are compared for all patients, the increase in both 5-HIAA and HVA is significant at the $p < .01$ level. The 5-HIAA showed a 45 percent increase, from 29.2 to 42.2 ng./ml. HVA showed a 150 percent increase, from 16.9 to 42.1 ng./ml. The MHPG levels increased from 7.5 to 14.2 ng./ml. This 90 percent increase in MHPG only approaches statistical significance ($p < .10$) because of the marked reversal in one patient.

Psychomotor Activity and Group Differences

Analysis of our entire population of patients with affective illness suggests that the levels of both 5-HIAA and HVA in the CSF parallel the patients' general level of behavioral activity before the LP is performed (figure 1). Depressed patients had low levels of psychomotor activity and had the lowest CSF amine metabolite levels; hypomanic and manic patients were more active and had intermediate amine metabolite levels; patients simulating mania, who were the most intensely active over a brief period of time, had the highest CSF amine metabolite levels.

The direction of the amine metabolite differences within diagnostic groups lends support to the suggestion that the level of psychomotor activity is an important factor in determining the level of amine metabolites. Hypomanic patients (those with mania ratings of less than 4) had normal amine metabolite values, while acutely disturbed and psychotic patients (those with mania ratings of 4 or more), for whom total bed rest could often not be maintained, had higher 5-HIAA and HVA values, similar to those obtained after our study patients simulated mania (table 3). These differences were significant for both 5-HIAA and HVA ($p < .05$, one-tailed t test).

Table 3 summarizes these relationships of CSF amine

metabolite levels to activity. Physically hyperactive patients, those simulating mania, and severely manic patients all had high values in contrast to those from control, hypomanic, and depressed groups.

Within the larger group of depressed patients, agitated patients did not have significantly higher levels of amine metabolites than did predominantly retarded patients. There was no significant relationship between CSF amine metabolite levels and severity of depression.

DISCUSSION

These results indicate that experimentally induced increases in psychomotor activity significantly elevate the levels of 5-HIAA and HVA in the CSF. Activity also tends to elevate the CSF levels of MHPG. In addition, CSF 5-HIAA and HVA levels correlate with the degree of spontaneous psychomotor activity associated with different clinical states.

Increased mixing of ventricular-cisternal cerebrospinal fluid into the lumbar area as a secondary result of activity does not appear to account for all the observed changes. Moir and associates (27) reported that, in man, the ratio of ventricular to cisternal to lumbar concentration for 5-HIAA is 5.5 to 4.5 to 1 and for HVA it is 8.8 to 4.5 to 1. Data from NIMH suggest a ventricular to lumbar concentration ratio of 3 to 1 for 5-HIAA and 10 to 1 for HVA (20). Thus, if there were a greater mixing of CSF from ventricular and/or cisternal fluid into the lumbar region during hyperactivity, a modest increase in 5-HIAA and a more substantial increase in HVA would be expected; this is essentially what was observed in these patients.

On the other hand, MHPG, which does not have a demonstrable ventricular-lumbar gradient (20), also increased after activity. Cyclic-AMP, which does have a rostral-caudal CSF gradient (28) was not significantly altered by the simulation of mania in these patients (26). The levels of cyclic-AMP, in fact, showed a slight decrease rather than the increase that would be expected if CSF mixing were occurring. In addition, in our study the mean levels of CSF proteins were not different in the baseline LP (33.0 mg./100 cc.) than in the LP after simulating mania (32.2 mg./100 cc.). There is a reverse gradient for CSF protein, with an average of 17.1 mg./100 cc. in ventricular fluid, 18.3 mg./100 cc. in cisternal fluid, and 31.3 mg./100 cc. in lumbar fluid (29). Although this gradient is of relatively small magnitude and the potential for mixing is unknown, lumbar CSF proteins were not changed by the increased activity, as they could have been if the simulated mania substantially increased CSF mixing. Finally, activity studies in animals (30, 31) that showed changes directly in brain, where there is no consideration of CSF gradients, suggest that the increases in metabolites observed in the present study may be reflective of central amine changes and not merely the result of CSF mixing.

Although the condition of physical activity alone was sufficient to elevate the levels of amine metabolites, it is possible that mood elevation and the activation of verbal and psychological processes could also be sufficient to produce increases in amine metabolite levels. In an attempt to evaluate this possibility, patient 5, who later successfully simulated mania while active, was first asked to simulate mania while lying at bed rest. The patient was not able to achieve this mood state, suggesting that physical activity may have a facilitating influence on the initiation of mania-like mood states. It was also our clinical impression, however, that the degree of mood elevation during the simulation of mania was not clearly related to the degree of increase in amine metabolites.

Considerable evidence supports the conclusion that the increases in amine metabolites were not due to the two hours of sleep deprivation that the patients incidentally experienced during the experimental procedures. Patient 5, who unsuccessfully attempted to simulate mania while at bed rest, yet was also awake from 5 a.m., did not show major increases in amine metabolites (table 4). Patient 10, who was totally sleep-deprived for 26 hours as part of another study (but was maintained at bed rest from midnight until 9 a.m.), also showed no metabolite increases. Furthermore, patient 9, who was active from 8 a.m. to noon (so that no sleep deprivation was involved) showed elevated levels of metabolites similar to those of the other patients. Finally, Bowers and associates (9) have shown that the average amount of sleep during the six nights bracketing their LP testing was positively related to the CSF HVA levels, so that sleep deprivation associated with the simulation of mania might be expected to decrease rather than increase the HVA levels. Results from our laboratory indicate that there is

no correlation between the number of hours of sleep on the night before the LP and the CSF amine metabolite levels (19).

There is ample evidence from animal studies in the literature that brain turnover of norepinephrine, dopamine, and serotonin can be increased as a result of a variety of stresses (31). In a study pertinent to our experimental manipulation, Bliss and Ailion (30) have shown that both stress and physical activity, either alone or in combination, increase the levels of HVA in rat brain. The simulation of mania and activity in our study may have produced psychic as well as physical stress, although this was not apparent from the subjective reports of most patients. In favor of activity rather than stress in accounting for our data is the lack of change in amine metabolites in the patient who unsuccessfully attempted to simulate a manic mood while at bed rest, even though he reported the experience as stressful. Also, the patient who underwent the stress of 26-hour sleep deprivation showed no increases in CSF amine metabolites (table 4).

Since dopamine is the amine most closely associated with alterations in motor activity in animals (32), it is of interest that HVA showed the largest increases after simulated mania and activity. This is consistent with our finding that the CSF HVA levels differed in depression and mania, while the 5-HIAA levels did not. L-dopa, the precursor of dopamine, has induced behavioral activation and switches into hypomania in depressed patients (33, 34). It is likely that dopaminergic neurons are functionally related to psychomotor activity in man as well as in various animal species.

Taken together, the data presented in this study strongly suggest that psychomotor activity, especially physical activity, plays an important role in determining the levels of CSF amine metabolites in affective illness. The need for appropriate methodological controls for activity is underlined by these data. We suggest that the evaluation of biologic changes in simulated behavioral states might help to differentiate those changes primarily related to underlying psychiatric illness from those secondary to one or more of its behavioral manifestations. This theme will be elaborated in a subsequent paper (35).

Cerebrospinal Fluid Amine Metabolites in Affective Illness: The Probenecid Technique

BY FREDERICK K. GOODWIN, M.D., ROBERT M. POST, M.D., DAVID L. DUNNER, M.D., AND EDNA K. GORDON

Probenecid inhibits the removal of 5-HIAA and HVA (the major metabolites of serotonin and dopamine) from the cerebrospinal fluid. The accumulation of these metabolites following high doses of probenecid was studied in patients with affective illness in order to assess central amine function. The metabolite accumulation was increased by administering the appropriate precursors (which increase amine synthesis) and was decreased by administering specific synthesis inhibitors. Compared with controls, the depressed patients had low HVA accumulation, while addicts on methadone had low 5-HIAA accumulation. Within the group of depressed patients, HVA accumulation was higher in bipolar than in unipolar patients.

A LARGE BODY of evidence from animal studies indicates that the biogenic amines norepinephrine, dopamine, and serotonin act as central nervous system (CNS) neurotransmitters, particularly in those areas of the brain subserving "emotional" functions (1). Speculations that functional abnormalities in one or more of these neurotransmitter amines may be involved in human psychiatric states (particularly affective illness) have been based largely on indirect evidence from pharmacological studies in animals. For example, drugs that increase the functional levels of biogenic amines in the brain of experimental animals can alleviate some depressions, while drugs that deplete the levels of these amines have been reported to induce depression in some cases (2, 3). In addition it has been hypothesized on the basis of recent animal data that the phenomenon of addiction to narcotic drugs may involve central amine mechanisms (4). For example, Way and his colleagues (5) have presented evidence in studies of mice that the development of tolerance to chronic morphine administration is dependent on an increase in brain serotonin turnover.

However, direct data from patients concerning the relationship of CNS amine metabolism to psychiatric illness has been fragmentary and has mainly involved studies of amine metabolite levels in the cerebrospinal fluid (CSF) of depressed patients. In some studies (6–9), the CSF levels of 5-hydroxyindoleacetic acid (5-HIAA), the major metabolite of serotonin, have been reported to be lower in depressed patients than in various "control" groups; other investigators have found no significant differences (10–12). Levels of homovanillic acid (HVA), the major metabolite of dopamine, have been reported to be lower in depressed patients than in neurological controls by some investigators (10, 12), but not to be different from those of "controls" by others (11, 13). Similar confusion exists in relation to the levels of these metabolites in manic patients (6, 8, 10, 11). Levels of 3-methoxy-4-hydroxyphenylglycol (MHPG), the major metabolite of norepinephrine in the CNS, have been noted by our group to be lower in depressed patients than in normal subjects or manic patients (14), but others do not agree (15). We have discussed elsewhere (16) the variety of factors that probably contribute to the variability in the CSF levels of these metabolites as reported by various investigators. It has been proposed that more meaningful conclusions might be drawn about the functional state of a dynamic pool of biogenic amines if data concerning both the level and the rate of change were available.

In an attempt to develop a technique that might reflect the "turnover" of CNS amines, probenecid has been administered to patients by a number of investigators (10, 17–19). The rationale for the use of probenecid in the study of dopamine and serotonin turnover in the CNS is based on several findings: 1) probenecid can inhibit the renal transport of several organic acids, including 5-HIAA and HVA (20, 21); 2) these acids are removed from the CNS into the blood by an active transport mechanism similar to that found in the kidney (22); 3) inhibition of this transport by the administration of pro-

Based in part on a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

benecid causes linear elevations (over at least several hours) of 5-HIAA and HVA in the brain (23), ventricular fluid (24), and cisternal CSF (25) of a variety of animal species; and 4) the application of steady-state mathematical techniques indicates that the rate of elevation of acid amine metabolites after the administration of probenecid produces turnover values for the parent amines that are comparable to those obtained by other methods, such as amine accumulation following the inhibition of monoamine oxidase or amine depletion following the inhibition of synthesis (26).

In other words, the rate at which the amine metabolites accumulate after their exit is blocked directly reflects the rate at which the parent amine is being synthesized, utilized, and metabolized (turnover). The rapid and linear increase in 5-HIAA or HVA following large doses of probenecid in animals suggests that the blockade of transport has a rapid onset and remains essentially complete throughout the experiment. We have recently demonstrated that MHPG, the major metabolite of norepinephrine, does not accumulate to an appreciable degree in the CSF of patients receiving probenecid, and thus this technique is not useful in assessing CNS norepinephrine turnover (27).

In the initial attempts to use probenecid in the study of brain amines in humans, small doses of the drug were given over two to three days, producing only slight increases in 5-HIAA and HVA. In the animal studies, in which larger doses were given, the rate of increase of 5-HIAA in CSF was orders of magnitude greater than that reported in human subjects; this suggests that in these initial human studies the relatively low probenecid levels caused only a minimal, intermittent inhibition of acid metabolite transport out of the CNS.

We have previously reported a refinement of this technique in which larger and more frequent doses of probenecid were given to man, producing rapid and pronounced elevations of the acid metabolites of serotonin and dopamine (19). More recently Van Praag and his coworkers (28) have modified their original technique, employing doses approaching the range reported here.

The present study first examined the alterations in the probenecid-induced accumulation of 5-HIAA and HVA produced by amine precursors and synthesis inhibitors in order to provide evidence for the validity of this technique in the estimation of CNS amine turnover. The amine precursors L-dopa and L-tryptophan and the synthesis inhibitors alpha-methyl-para-tyrosine (AMPT) and parachlorophenylalanine (PCPA) were administered during clinical trials conducted for the purpose of evaluating their therapeutic effectiveness in depression and mania (29, 30). Then differences in the probenecid-induced accumulation of 5-HIAA and HVA were examined in different diagnostic groups—patients with affective illness, a small group of addicts on methadone, and normal controls. Within the group with affective illness, the diagnostic subgroups, severity of various symptoms, and response to treatment were examined in relation to the probenecid-induced alterations in CSF amine metabolites.

METHOD

Thirty-four patients with affective illness, eight heroin addicts on methadone, and eight normal controls[1] were studied on a metabolic research unit at the NIMH specifically designed for the collection of behavioral and biochemical data on a longitudinal basis. Subjects were limited to those who volunteered after a careful explanation of the procedures involved. The depressed patients had symptoms that ranged from moderately severe to severe, including psychomotor retardation or agitation, anorexia, weight loss, sleep disturbance, and depressive thought content, often of psychotic proportions; they were all free of extenuating medical problems. The diagnostic criteria and behavioral rating system used have been previously described (31).

All subjects except those on methadone were drug-free for at least two weeks before the study began. During the study, all foods in the diet that might affect indoleamine or catecholamine metabolism were restricted. The initial lumbar puncture (LP) was performed at 9 a.m., with the patients in the lateral decubitus position. The second LP was done at 3 p.m. on the following day; during the 18 hours preceding the second LP, 100 mg./kg. of probenecid was administered in divided doses (9 p.m., 2 a.m., 7 a.m., and 12 noon). Patients were kept at bedrest for eight hours prior to the initial LP and throughout the time of probenecid administration.

For the studies focused on drug effects, the entire probenecid procedure was repeated in an identical fashion, so that placebo and drug data could be compared for each patient. The administration of other drugs, including aspirin and sedatives, was carefully avoided throughout the study period. In order to have some data for direct comparison with the previously studied control group, a small number of depressed and methadone patients were given an LP after only nine hours of receiving probenecid. In this group the dose averaged 115 mg./kg.

All LPs were nontraumatic; the samples were collected in 20 mg. of ascorbic acid per 10 ml. of fluid and stored at −20 C until analyzed. Levels of 5-HIAA and HVA were determined using the first 8 ml. of CSF obtained, according to modifications of the methods of Ashcroft and Sharman (32), Gerbode and Bowers (33), and Anden and associates (34). Except as otherwise indicated, statistical comparisons were done by Student's t test for grouped or paired data.

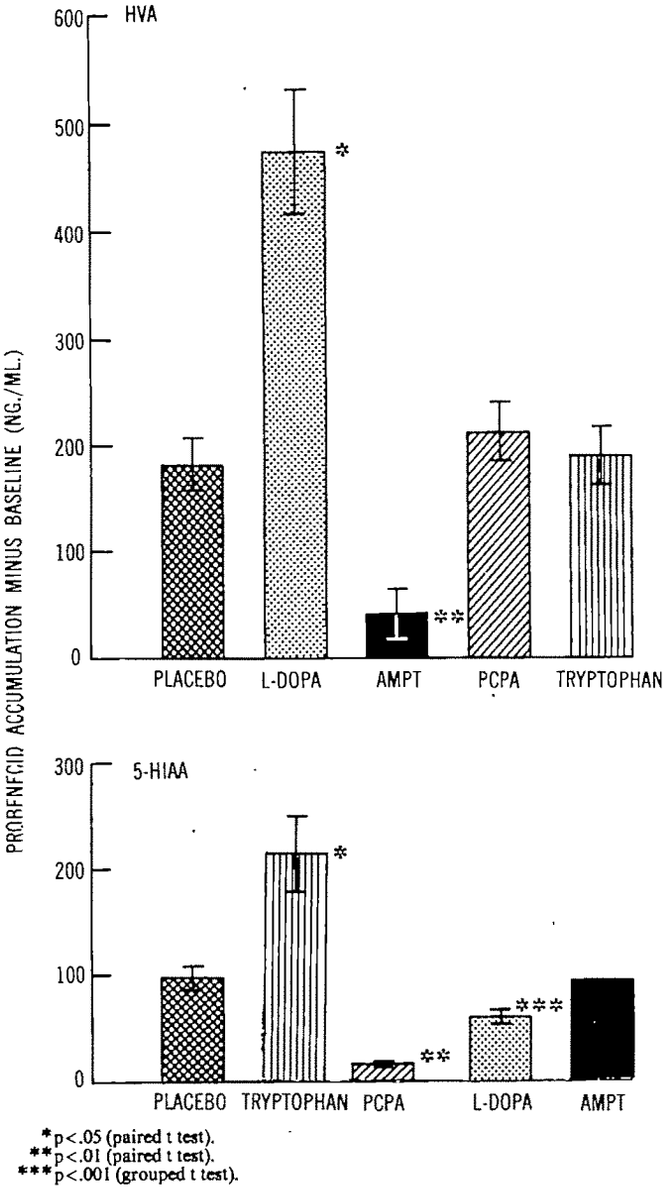
RESULTS

Effects of Amine Precursors and Synthesis Inhibitors

If the probenecid-induced accumulation of 5-HIAA and HVA in the CSF does in fact reflect the turnover (and therefore also the synthesis) of serotonin and dopamine in the CNS, then this accumulation should be increased by compounds that increase the synthesis of the

[1] Studied in collaboration with T.N. Chase.

two amines and decreased by inhibitors of amine synthesis.



To test this hypothesis, four drugs that specifically increase or decrease the synthesis of dopamine or serotonin in the CNS were studied for their effects on the probenecid-induced accumulation of HVA and 5-HIAA. The results are summarized in figure 1. In this figure the bars represent the amount of metabolite accumulated, i.e., the level attained while the patient was on probenecid minus the baseline level before the administration of probenecid. In each instance the comparison is made between the probenecid-induced accumulation during the pre-drug period and the accumulation while that same patient was receiving an amine precursor or synthesis inhibitor.

L-dopa, the amino acid precursor of dopamine, was administered to five patients in combination with alpha-methyl-dopa-hydrazine (MK485), a selective inhibitor of peripheral dopa decarboxylase that potentiates the uptake of administered dopa into the brain (29). L-dopa administered in this way is known to substantially increase brain dopamine synthesis. As is evident from the figure, L-dopa produced a large increase in the HVA accumulation and a moderate but significant decrease in 5-HIAA accumulation. On the other hand, pretreatment of three patients with AMPT, a specific inhibitor of dopamine synthesis, both peripherally and centrally (30), almost completely abolished the probenecid-induced accumulation of HVA; 5-HIAA accumulation was unaffected by AMPT.

L-tryptophan, the amino acid precursor of serotonin, was administered to five patients and caused a large increase in 5-HIAA accumulation but did not significantly affect HVA accumulation. On the other hand PCPA, a specific inhibitor of serotonin synthesis (35) administered to two patients, virtually eliminated the probenecid-induced accumulation of 5-HIAA; HVA accumulation was not affected by PCPA.

Thus for both serotonin and dopamine the appropriate amine precursor increased the amine metabolite accumulation, while the specific inhibitors of synthesis decreased the metabolite accumulation during administration of probenecid.

***p<.001 (grouped t test).

Baseline Levels of 5-HIAA and HVA in Different Groups

As illustrated in table 1, the baseline levels of 5-HIAA revealed no significant differences between the various diagnostic groups. In regard to HVA, the depressed patients tended to have lower CSF levels when compared with hypomanic patients ($p < .05$) or normal controls ($p < .10$).

Probenecid-Induced Alterations in 5-HIAA and HVA

A number of patient variables were examined for their possible effects on the data obtained. The correlations are summarized in table 2. Although a wide age range existed in our patient population (the mean ages for each group were: controls=29, patients with affective illness =43, addicts=26), there was no correlation between age or sex and the probenecid-induced accumulation of 5-HIAA or HVA. In our initial studies, using a fixed dose of probenecid, a significant negative correlation was found between the patient's weight and the accumulation of amine metabolites while on probenecid (19). As table 2 shows, when the drug is administered on a milligram per kilogram basis there is no significant relationship between amine metabolite accumulation and either patient weight or the absolute dosage level of probenecid. Because the drug was not available in units smaller than 250 mg., the level of 100 mg./kg. represented an approximation. The actual dose range was 85–118 mg./kg., accounting for the small but nonsignificant positive correlation between dose per kilogram and metabolite accumulation. The marginal nature of this correlation is consistent with earlier work showing that

TABLE 1

The Effects of Probenecid on CSF Amine Metabolites in Different Diagnostic Groups

†Significantly different from the control group ($p<.01$).

at levels above 90 mg./kg. the relationship between probenecid dose per kilogram and metabolite accumulation falls off sharply (19).

Table 1 summarizes the data on the probenecid-induced accumulation of 5-HIAA and HVA in controls, patients with affective illness, and addicts on methadone. For comparisons with the control group, only the data from the smaller number of depressed or addict patients studied at nine hours can be used. The administration of probenecid resulted in significantly lower 5-HIAA accumulation in the addicts on methadone, compared with either the controls ($p < .05$) or the patients with affective illness studied at 18 hours ($p < .025$). The accumulation of 5-HIAA in the depressed patients was lower than in the controls at the nine-hour point in spite of the fact that the depressed patients received about 20 percent more probenecid than the controls on a milligram per kilogram basis. With the small number of patients studied at this time point, the difference did not reach statistical significance. The 5-HIAA accumulation at the 18-hour point was virtually identical in the depressed and manic groups; unfortunately no data were available from the control group at the 18-hour point.

The probenecid-induced accumulation of HVA in the different diagnostic groups is also summarized in table 1. Comparing those groups studied after nine hours of probenecid, the depressed patients had the lowest levels of HVA, less than half that accumulated by the controls ($p < .01$), in spite of the somewhat larger dose of probenecid in the depressed group. The addict group also had significantly lower HVA accumulation than the controls ($p < .05$). In spite of the lower baseline level of HVA in the depressed patients, there was no significant difference between the depressed and hypomanic patients in the level of HVA after administration of probenecid.

Within the group of depressed patients a number of factors relating to diagnoses, severity of depression, and drug response were analyzed for possible relationships to the probenecid-induced accumulation of 5-HIAA and/or HVA. These analyses included only the patients studied with the standard 18-hour procedure; they are summarized in tables 2, 3, and 4.

There was no significant relationship between the severity of depressive symptoms (global depression, agitation, or retardation) and the amine metabolite accumulation, but there was a trend for patients with more severe illness to have lower amine metabolite accumulation (table 2).

Agitation	−.26	−.26
Retardation	−.31	.10

TABLE 3

CSF Levels of 5-HIAA and HVA After Probenecid Administration in Subgroups of Depressed Patients

Diagnostic Subgroups	N	5-HIAA (ng./ml.±S.E.M.)	HVA (ng./ml.±S.E.M.)
Bipolar I	8	144±7	267±32*
Bipolar II	7	128±11	180±30
Unipolar	11	127±13	173±22

*Significantly different from the unipolar group ($p<.05$, Student's t test).

The depressed patients were classified as either bipolar or unipolar on the basis of the presence or absence of a prior history of mania as documented by hospitalization; patients with a history of recurrent depression interspersed with periods of abnormal mood elevation but not mania were separately classified as "bipolar II," according to previously described criteria (36). As indicated in table 3, bipolar patients had significantly larger HVA accumulations than the unipolar patients. There were no differences in 5-HIAA accumulation.

The patients were subdivided according to their subsequent response to antidepressants, using both lithium and tricyclic antidepressants and employing criteria previously described (37). The CSF amine metabolite data for these groups are summarized in table 4. When compared with the lithium nonresponders, those depressed patients who showed a therapeutic response to lithium had significantly lower levels of both 5-HIAA ($p < .02$) and HVA ($p < .01$) after receiving probenecid. On the other hand, there was a trend for those who responded to the tricyclic antidepressants to have somewhat higher levels of 5-HIAA and HVA after receiving probenecid than the nonresponders, although this difference was not significant.

*Significantly different from lithium responders ($p<.02$, Student's t test).
**Significantly different from lithium responders ($p<.01$, Student's t test).

DISCUSSION

How adequately does the probenecid-induced accumulation of 5-HIAA or HVA in the lumbar CSF of patients reflect alterations in the metabolism or turnover of serotonin or dopamine in the brain? We have detailed elsewhere the potential difficulties in the interpretation of lumbar CSF amine metabolite data (19, 38); these problem areas include the concentration gradient for 5-HIAA and HVA from relatively high levels in brain ventricular fluid to relatively low levels in lumbar fluid, the transport time required for amine metabolites formed in brain to reach the lumbar CSF, and finally the possible contribution of local spinal cord serotonin metabolism to the CSF 5-HIAA levels.

The concentration gradient is maintained by the active removal of 5-HIAA and HVA as they move caudally from the ventricle to the lumbar sac (39). High doses of probenecid reduce the gradient by inhibiting this removal process, allowing amine metabolite levels in the lumbar CSF to more truly reflect ventricular levels. The lumbar CSF levels of 5-HIAA and HVA found after the administration of probenecid in the present study are equivalent to the levels of these metabolites in human ventricular fluid (40).

The effects of amine precursors and synthesis inhibitors on the probenecid-induced accumulation of 5-HIAA and HVA further support the validity of these data as a reflection of brain amine metabolism. Animal data indicate that there is little or no dopamine in the spinal cord, a finding consistent with the report of Curzon and associates (41), recently confirmed by our group (42), that patients with a blockage of the spinal fluid flow from above have little or no HVA in their lumbar CSF. Since AMPT, a specific inhibitor of brain dopamine synthesis, virtually eliminates the probenecid-induced accumulation of HVA in the lumbar CSF, it seems reasonable to conclude that the probenecid-induced HVA accumulation (without AMPT) reflects brain dopamine synthesis. A similar finding with AMPT has recently been reported by Sjostrom (43).

The interpretation of the 5-HIAA data is more complex because some of the 5-HIAA in the lumbar CSF appears to have its origin in the spinal cord (41, 42). Nevertheless, the levels of 5-HIAA after the administration of probenecid should represent a relatively greater contribution from the brain by virtue of the decreased removal of this metabolite along the ventricular-lumbar axis.

Previous reports of a high correlation between plasma (or CSF) probenecid levels and amine metabolite accumulation (17, 44) have raised the possibility that differences in probenecid absorption or metabolism could account for some of the differences observed in amine metabolite accumulation. This caution is relevant only when the accumulation of 5-HIAA and HVA are both altered in the same direction and to approximately the same degree, that is, when the 5-HIAA/HVA ratio is not altered (18). Sjostrom recently reported (44) that the high correlation between CSF probenecid levels and 5-HIAA accumulation ($r = 0.86$) begins to drop off at a CSF probenecid concentration above 4–5 μg./ml. Preliminary data indicate that the relatively high dosage schedule employed in the present studies has resulted in CSF probenecid levels of more than 5 μg./ml., with plasma levels in the range of the 300–400 μg./ml. In our patients, therefore, variations in probenecid absorption were less likely to make a meaningful contribution to variations in amine metabolite accumulation.

In light of the above considerations it is not surprising that the probenecid technique has "uncovered" a number of alterations in amine metabolites that were not evident from the baseline CSF metabolite levels. In patients with affective illness, 18 hours of probenecid administration (100 mg./kg.) increased the levels of 5-HIAA 400 percent and of HVA 1000 percent over baseline. At these higher levels of accumulation, contrary to the finding of Bowers (18), we did not find a significant correlation between baseline and post-probenecid levels of amine metabo-

lites. Thus, the high-dose probenecid technique does not appear to merely produce an amplification of the baseline values but probably reflects a different parameter, i.e., amine turnover.

When compared with controls and patients with affective illness, the addicts on methadone showed significantly less accumulation of 5-HIAA, a finding in agreement with the report of Bowers and associates (45). In animal studies, the initial reports of increased amine turnover produced by narcotic drugs, especially increases in serotonin turnover (5, 46) (in contrast to our clinical findings), have recently been challenged (47, 48), and the possibility of species variation has been noted.

The probenecid HVA data suggest that bipolar patients may have more rapid dopamine metabolism than unipolar patients, a finding of relevance to some pharmacological data recently reviewed by Murphy (49). Our probenecid findings add to a growing body of data indicating that unipolar and bipolar depressions may be biologically separable.

The question of whether HVA accumulation in depressed or manic patients receiving probenecid is different from that of controls cannot be finally resolved until further data are obtained. The data available (at the nine-hour point) do however suggest a lowered HVA turnover in the depressed patients, which is in agreement with previous reports (10, 13).

Our finding that the baseline levels of 5-HIAA in the CSF of depressed or manic patients was not different from that of controls is in agreement with some previous studies (6–9) but not with others (10–12). In regard to probenecid-induced accumulation of 5-HIAA, some investigators have found it reduced in depressed patients (10, 13), while others have not (18). Our own probenecid 5-HIAA data are not yet conclusive. Thus, a conclusion that serotonin turnover is decreased in affective illness is premature.

L-Dopa, Dopamine, and Hypomania

BY DENNIS L. MURPHY, M.D., FREDERICK K. GOODWIN, M.D., H. KEITH H. BRODIE, M.D., AND WILLIAM E. BUNNEY, JR., M.D.

Greater urinary excretion of dopamine during L-dopa administration was observed in bipolar than in unipolar depressed patients. The authors suggest that increased levels of brain dopamine may play a role in the development of hypomania and mania, since there is a tendency for bipolar patients to regularly develop hypomanic episodes during L-dopa treatment and since evidence from animal studies indicates that increased brain dopamine is highly correlated with increased psychomotor activity.

BRIEF EPISODES of hypomania and mania have been observed in most bipolar depressed patients receiving L-dopa, the amino acid precursor of the catecholamines dopamine and norepinephrine (1). Similar episodes occurred significantly less frequently in unipolar depressed patients and are an uncommon side effect of L-dopa treatment in patients with Parkinson's disease (1, 2). It is not known whether this predilection for bipolar depressed patients to develop hypomanic episodes during L-dopa administration is due to a greater psychological or central nervous system (CNS) sensitivity to the stimulant effects of this drug or to altered L-dopa metabolism in these patients.

The characteristics of cortical evoked responses in bipolar patients (3) as well as their greater sensitivity to behavioral activation by other drugs besides L-dopa (4, 5) suggest that bipolar patients may exhibit altered CNS modulation of extrinsic stimuli (2). On the other hand, the differences in the behavioral response to L-dopa between bipolar and unipolar depressed patients could be secondary to differences in the metabolism of L-dopa in these two populations. In this regard, Takahashi and associates demonstrated that manic-depressive patients, whether depressed or manic, had much higher and more sustained elevations of plasma levels of another amino acid, L-tyrosine, following an oral load test (6). In animals, the excitant effects of L-dopa are closely related to dosage and appear to be directly proportional to the associated elevation in brain dopamine levels (7).

The authors have all been with the Section on Psychiatry, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, Md., where Drs. Murphy and Goodwin are Clinical Research Unit Chiefs, Dr. Brodie was Clinical Associate, and Dr. Bunney was Chief; Dr. Brodie is now Assistant Professor of Psychiatry, Stanford University Medical School, Stanford, Calif., and Dr. Bunney is now Director, Division of Narcotics and Drug Abuse, NIMH. TABLE 1
Characteristics of Depressed Patients Who Received Chronic L-dopa Treatment

Category	Depressed Patients With Hypomanic Episodes (N=4) Mean ± S.E.M.	Depressed Patients Without Hypomanic Episodes (N=4) Mean ± S.E.M.
L-dopa dosage (mg./kg.)	63 ± 13	74 ± 14
Treatment days	14 ± 5	11 ± 4
Age	48 ± 3	43 ± 10
Sex: male	1	1
female	3	3

To evaluate whether altered L-dopa metabolism might have contributed to the development of hypomania in the bipolar patients, measurements were made of the urinary excretion of dopamine, of homovanillic acid (HVA)—the major metabolite of dopamine—and of unmetabolized L-dopa in those patients who developed hypomania and in a control group of unipolar patients who did not develop hypomania.

METHOD

The assay methods (8) and the details of the clinical trial with L-dopa (9) are described elsewhere. The bipolar depressed patients were all characterized by a history of mania severe enough to require hospitalization or specific treatment. Both the bipolar patients and the unipolar patients (who did not have a history of mania) were rated as equally severely depressed on the Bunney-Hamburg Scale (10) at the time of drug treatment. Neither the patients nor the staff responsible for the behavioral rating of the patients (10, 11) were aware whether the capsules given were L-dopa or placebo. Any day with an elevated rating on the mania scale and one day preceding and following such days were omitted from the analysis.

The initial study utilized data obtained for the purpose of establishing an L-dopa dose-response relationship and consisted of three to seven 24-hour urine samples from each of four depressed patients who developed hypomania and from four patients who did not develop hypomania. Although the samples had originally been chosen only as representative of low, medium, and high dosage ranges for each patient, and not for the bipolar-unipolar comparison, the two patient groups were found to be very similar when age, sex, and the dosage and duration of L-dopa treatment were compared, using the averages from the days of the catecholamine assays (table 1).

RESULTS

As indicated in table 2, the patients who developed hypomania excreted more than twice as much dopamine and L-dopa during L-dopa treatment as did the unipolar patients, although the HVA levels were much less dissimilar. A comparison of the least-square regression plots of dopamine excretion versus L-dopa dosage for the two groups (figure 1) revealed significantly different slopes ($p < .01$) and did not suggest that the nonsystematic selection of samples for analysis had biased the data.

A replication of these results was attempted by studying the 24-hour urinary excretion levels of dopamine, L-dopa, and HVA following the administration of an acute L-dopa load of 2 gm. per day (500 mg. at 9 a.m. and at 1, 4, and 9 p.m.) in six bipolar and six unipolar hospitalized depressed patients. Although the initial results (see figure 1) would have predicted greater differentiation of the two patient groups if higher L-dopa doses were used, nausea and other side effects prohibited initial doses over 2 gm. per day. Nonetheless, as indicated in table 3, urinary excretion of dopamine was again found to be two to three times greater in the bipolar patients.

After the acute L-dopa load, the differences in L-dopa and HVA excretion were nonsignificant. Prior to treatment with L-dopa, the dopamine and HVA excretion rates were not significantly different in the two groups (table 3). Age, sex, and weight were similar in both groups. There were no rated changes in mood or behavior in either group of depressed patients when the day of L-dopa administration was compared with the two days on placebo before and after the administration of L-dopa.

DISCUSSION

These results indicate that bipolar depressed patients

excrete more urinary dopamine in response to an L-dopa load than do unipolar depressed patients, and that this difference increases with increasing L-dopa dosage. The urinary dopamine values for the bipolar and unipolar depressed patients fall at the upper and lower limits, respectively, of those observed in parkinsonian patients treated with L-dopa (12). Strom-Olsen and Weil-Malherbe (13), Sloane and associates (14), and Messiha and associates (15) have documented increased rates of urinary dopamine excretion during spontaneously developing mania, but urinary dopamine excretion in bipolar versus unipolar patients during depression has not previously been compared.

Abundant evidence from studies of experimental animals and patients with Parkinson's disease indicates that psychomotor activity can be closely correlated with brain dopamine levels. In animals, L-dopa administration leads to marked elevations in brain dopamine, with a close correlation between dopamine levels and increased motor activity (7); in contrast, brain norepinephrine levels are only minimally increased, or may actually be reduced, during L-dopa treatment (7, 16).

The development of hypomania during L-dopa treatment in eight out of nine bipolar depressed patients but only one out of 12 unipolar patients, as reported previously (1), together with the present results showing increased dopamine excretion in the bipolar patients during L-dopa administration, suggests that the increased psychomotor activity observed during hypomania and mania might represent the behavioral effects of increased levels of dopamine formed from L-dopa.

It remains to be determined whether this difference in L-dopa metabolism can be related to specific (6) or nonspecific alterations in the absorption or excretion of amino acids, to reported enzyme differences between these two groups (17, 18), or to other factors capable of influencing catecholamine metabolism. For example, it is not possible to exclude the possibility that subtle increases in motor activity in the bipolar patients might have led secondarily to the increased rates of urinary dopamine excretion observed in this study. Assessment of this question requires the measurement of dopamine and its metabolites in areas closer to the central nervous system.

FIGURE 1
Comparison of Dopamine Excretion Rates in Two Groups of Depressed Patients

SUMMARY

During L-dopa administration, bipolar depressed patients excreted more urinary dopamine than did unipolar depressed patients. This difference increased with increasing L-dopa dosage. Since the bipolar patients also exhibited a differential sensitivity to the development of hypomania and mania during L-dopa treatment, these results suggest that changes in dopamine metabolism may be implicated in the development of hypomania and mania.

The Pharmacology of Tardive Dyskinesias

BY HAROLD L. KLAWANS, JR., M.D.

The activity of dopamine at certain striatal dopamine receptors is related to the appearance of tardive dyskinesias in man. By analogy to Huntington's chorea and L-dopa-induced dyskinesias in parkinsonism, it appears that tardive dyskinesias are related to increased responsiveness of dopamine receptor sites as a result of neuroleptic-induced denervation hypersensitivity. It has been demonstrated that anticholinergic drugs worsen tardive dyskinesias in patients who have this disorder. It also appears that anticholinergic drugs decrease the threshold for tardive dyskinesias and thereby increase the incidence of this disorder. This implies that centrally active anticholinergic agents should not be used as a routine adjunct to neuroleptic therapy.

LINGUAL-FACIAL-BUCCAL dyskinesias are abnormal, involuntary, persistent movements of the tongue, lips, and facial muscles (1). Movements of this nature were first described as an integral part of the hyperkinesia of Huntington's chorea and other choreatic states. They occur as a rare spontaneous movement disorder in elderly patients without known cause; the term bucco-lingual masticatory or oral masticatory syndrome has been employed to describe this syndrome. It is quite likely that in this setting these movements may be related to senile chorea. Similar movements are frequently seen as a side effect of long-term L-dopa therapy of parkinsonism. In the last two decades analogous movements have been observed as a late, or tardive, and frequently permanent complication of long-term neuroleptic therapy (2–4). The term tardive dyskinesia is usually used to describe this disorder.

The pathogenesis and pathophysiology underlying these abnormal movements remain a matter of conjecture in all four settings. The relationship of a variety of pharmacologic agents to all of these has certain implications as to the pathophysiology of these movements. These observations shed some light on the mechanism that triggers the movements seen in tardive dyskinesia. Inferences as to the etiology and therapy of tardive dyskinesias can also be drawn from these observations.

Tardive dyskinesias occur in patients who have been treated with large doses of neuroleptics for long periods of time (4). It is possible that brain damage may in some cases predispose a person to dyskinesia, but brain damage does not seem to be a necessary factor. Tardive dyskinesias appear only late in the course of neuroleptic therapy. Lingual-facial-buccal movements are the commonest hyperkinesia seen in this syndrome, but limb and

Dr. Klawans is Associate Attending Neurologist, Department of Neurological Sciences, Rush-Presbyterian-St. Luke's Medical Center, Chicago, Ill. 60612.

truncal chorea also occur (5). These movements may persist for years and may even become permanent despite the discontinuation of the drug (6–9). Often these dyskinetic movements first appear after a reduction in dosage or after discontinuation of phenothiazine therapy (3, 10).

The neuroleptics that have been reported to produce tardive dyskinesias after prolonged usage are the same agents that regularly result in drug-induced parkinsonism. Van Rossum (11) has hypothesized that chlorpromazine and other neuroleptics act by blocking dopamine receptors in the central nervous system. The competitive blockade by neuroleptics of dopaminergic receptors has been implicated as the basis of neuroleptic-induced parkinsonism (12). Neuroleptics, by instituting a blockade of these receptors, may produce a "chemical denervation" of the dopamine receptors of the striatum. If the blockade is complete at any receptor site, then this receptor is prevented from receiving its normal neurotransmitter (dopamine) input.

It is possible that after such prolonged chemical denervation some receptors may develop denervation hypersensitivity. Neurons whose dopamine receptors have developed this denervation hypersensitivity may respond in an abnormal manner to any dopamine that reaches these receptors. It is quite possible that tardive dyskinesias may be the overt manifestation of the abnormal response of such neurons.

The phenomenon of denervation hypersensitivity is well known in peripheral receptor sites, and the experimental work of Ohye and associates (13) on the nigrostriatal pathway suggests that an analogous phenomenon may occur centrally. The nigrostriatal pathway is composed of neurons whose cell bodies are the melanin-containing neurons of the substantia nigra and whose axon terminals are spread diffusely throughout the ipsilateral striatum (caudate and putamen). The neurons of the substantia nigra influence the neurons of the striatum by releasing dopamine onto them. When the nigrostriatal pathway is destroyed, the amount of dopamine available to act at the striatum is markedly diminished. Ohye and associates (13) found that when one putamen is dopaminergically denervated by the interruption of the ipsilateral nigrostriatal pathway, the rate of spontaneous firing of that putamen is markedly increased. This may be related to the observation that the majority of striatal neurons are inhibited by dopamine (14, 15). The increased rate of firing seen after unilateral interruption of the nigrostriatal pathway may represent a release from such inhibition.

Ohye and associates (13) also found that application of L-dopa to the putamen on the side of the lesion produced a marked and rapid increase in the rate of firing of that putamen. An increased rate of firing due to the application of L-dopa is seen only in the denervated putamen, implying that the neurons are reacting abnormally to L-dopa (dopamine) as a result of their partial denervation. This study provides evidence in support of the theory that denervation can bring about alterations in receptor site sensitivity and responsiveness to dopamine in the central nervous system.

L-DOPA-INDUCED DYSKINESIAS

There is also clinical evidence which suggests that receptor site sensitivity to neurotransmitters may be altered in other disease states that show lingual-facial-buccal dyskinesias similar in appearance to those seen in tardive dyskinesias. The L-dopa-induced dyskinesias in parkinsonism are thought by several workers to be an example of such denervation hypersensitivity. Cotzias and associates (16) proposed that the dyskinesias are not inherent in L-dopa itself but are a result of the "interaction of the drug with the pathological parkinsonian neurosubstrate." The low incidence of L-dopa-induced dyskinesias in normal individuals (17) suggests that the occurrence of the L-dopa-induced dyskinesias in parkinsonian patients is a result of the action of dopamine upon neurons that are characteristic of the brains of these patients. These neurons are apparently altered in a manner that increases their susceptibility to L-dopa-induced abnormal movements. It is possible that the mechanism underlying such an alteration of neuronal response to dopamine is the development of denervation hypersensitivity of the dopamine receptors.

Degeneration of the neurons of the substantia nigra is the most consistent pathologic alteration in parkinsonism (18). This degeneration of the nigrostriatal pathway produces a denervation of the striatal dopamine receptors. As a result of this denervation these receptors may go through a stage when they are hypersensitive to dopamine. L-dopa therapy could activate these hypersensitive receptors excessively and lead to dyskinesias. The lower incidence of dyskinesias on the less involved side in hemi-parkinsonism and the failure to produce dyskinesias in subjects without parkinsonism are consistent with the hypothesis that there must be significant dopamine denervation and a resulting hypersensitivity of the dopamine receptor before L-dopa-induced dyskinesias can occur.

It is unreasonable to maintain that L-dopa would never produce abnormal movements in normal individuals. "Normal" here would mean individuals who have no signs, symptoms, or history of extrapyramidal tract disease and who have never received phenothiazines. Neuronal degenerative changes of the striatum do occur during the aging process, and movements similar to those induced by L-dopa can and do occasionally occur spontaneously in older people. If it is assumed that dopamine produces these movements, L-dopa may bring them out in some percentage of elderly patients. It is also possible that large doses may occasionally elicit these movements in younger patients, but this is rare.

The theory that denervation hypersensitivity of dopamine receptors predisposes the system to abnormal receptor response is incomplete in that it disregards the observation that there are two different sets of dopamine receptors within the striatum. The initial studies on the

striatum emphasized that dopamine has an inhibitory effect on most striatal neurons (19). Recent work has shown that a significant percentage of the dopamine-responsive caudate neurons are actually facilitated by dopamine. In one such study, York (20) found that following the administration of iontophoretic dopamine, 53 putamen neurons showed facilitation, while 37 putamen neurons showed inhibition.

TWO TYPES OF RECEPTORS

The various physiological studies suggest that there are two separate nerve cell populations in the striatum: a dopamine-facilitated nerve cell population, which possesses predominantly or exclusively facilitory dopamine membrane receptors, and a dopamine-inhibited nerve cell population, with predominantly or exclusively inhibitory dopamine membrane receptors. It has been suggested that in Huntington's chorea the predominant defect occurs at the dopamine-facilitated neuron (21).

Pathologic evidence suggests that the small striatal neurons are dopamine-facilitated and that their involvement in Huntington's chorea is directly related to the production of chorea (21). The larger striatal neurons are dopamine-inhibited, and involvement of these cells in Huntington's chorea is manifested by hypokinesia and rigidity (22). It has been proposed that dopamine initiates chorea as a result of the altered response of dopamine-facilitated striatal neurons to normal amounts of this transmitter (23). In contrast to normal dopamine-facilitated neurons, the altered neurons are thought to discharge abnormally and perhaps hypersynchronously in response to dopamine stimulation. This type of response could produce the choreiform movements seen in Huntington's chorea and perhaps in tardive dyskinesia.

The existence of two populations of dopamine receptors that respond differently to the same neurotransmitter is not surprising, since the response of a receptor to a transmitter is a property of the receptor site and not of the transmitter molecule. The differences between these two types of receptors is significant in the pathophysiology of tardive dyskinesias. The two types of dopamine receptors are not equally susceptible to neuroleptic-induced blockade; the dopamine-facilitated neurons are blocked by levels of haloperidol or chlorpromazine that do not block the action of dopamine at dopamine-inhibited receptor sites.

This observation, together with the observation that tardive dyskinesias can occur independently of drug-induced parkinsonism, suggests that the drug-induced hyperkinesia is related to receptors that are not identical to those related to drug-induced, and presumably idiopathic, parkinsonism. Tardive dyskinesia may be visualized as an abnormally hyperactive response of the dopamine-facilitated receptor to dopamine, while drug-induced parkinsonism is related to a lack of response of the dopamine-inhibited receptors to dopamine.

Prolonged denervation of dopamine receptors may lead to prolonged or permanent abnormalities of these receptors. This may explain the often prolonged or permanent nature of these dyskinesias. Finally, the fact that phenothiazine-induced dyskinesias often make their first appearance after dose reduction or drug withdrawal could be explained by the assumption that a decrease in the striatal level of the neuroleptic would permit more of the dopamine to reach the sensitized dopamine receptors. The occurrence of these movements during neuroleptic therapy suggests that the competitive blockade can be overcome by endogenous dopamine.

Reserpine can produce a state of rigidity and akinesia resembling parkinsonism (24). In this way it resembles phenothiazines. However, reserpine does not induce tardive dyskinesias. This can be explained by its mechanism of action. The main action of reserpine is to prevent the storage of dopamine in intraneuronal granules by blocking the uptake into these granules (25). In this way, reserpine depletes the brain of dopamine and may produce akinesia and rigidity. However, it does not block dopamine receptors and consequently does not produce a "chemical denervation" of the receptors. If denervation hypersensitivity is significant in the production of tardive dyskinesias, reserpine would not be expected to produce tardive dyskinesias.

If receptor-site hypersensitivity to dopamine is causally related to the production of these abnormal movements, these movements should be increased by L-dopa, which increases the striatal dopamine concentration. This has been the experience of Hippius and Logemann, who studied a large group of patients with various tardive dyskinesias (26). When given single slow intravenous injections of 100 mg. of L-dopa, 12 of these 40 patients developed worsening of the abnormal movements. These authors felt that the enhancement of the hyperkinesias by L-dopa was related to the effect of L-dopa on the extrapyramidal system. It is most probable that the exacerbation of these movements by small doses of L-dopa is related to receptor-site hypersensitivity to dopamine.

AN EXAMPLE OF HYPERSENSITIVITY

The relationship of L-dopa, and presumably dopamine, to tardive dyskinesia is further exemplified by the patient described by Klawans and McKendall (27). They observed a single patient with persistent neuroleptic-induced tardive dyskinesias who had been placed on L-dopa. After she had received L-dopa for a few days, her facial dyskinesias increased markedly and she developed severe choreoathetotic movements of the extremities and trunk. Despite the discontinuation of L-dopa, the involuntary movements persisted for several weeks. The worsening of the patient's movement disorder by the institution of L-dopa therapy suggests that dopamine is in some way related to the pathogenesis of the abnormal movements. The level of homovanillic acid in the patient's cerebrospinal fluid was normal and suggested that there was a normal turnover of dopamine. This is evidence that the patient's abnormal movements were related to hyper-

sensitivity to dopamine rather than to increased dopamine synthesis.

This patient's movements later responded to treatment with haloperidol. The improvement of the movements following dopaminergic blockade by haloperidol is consistent with the observation of Delay and Deniker (28) that reinstitution of neuroleptics is the most successful means of suppressing tardive dyskinesias and also supports the importance of dopamine in the pathophysiology of the movements. Other therapeutic approaches have been tried. Villeneuve and Boszormenyi have shown that reserpine is of some value in the treatment of this disorder (29). Brandrup (30) and MacCollum (31) have used tetrabenazine to ameliorate these movements. Both tetrabenazine and reserpine deplete cerebral and striatal dopamine concentrations and thereby decrease the amount of dopamine available and able to act at dopamine receptors.

The discussion of lingual-facial-buccal dyskinesias has thus far focused on the striatum and the dopaminergic input to the striatum. There are at least two other neuronal systems that are known to have inputs in the striatum. These are the serotonergic system and the cholinergic system. The cholinergic system acting at the striatal cholinergic receptors has been shown to exert an influence on the striatum opposite to that of dopamine (20). A balance of dopaminergic and cholinergic influence upon the striatum is necessary for normal functioning of the striatum (12, 14). Since the cholinergic and dopaminergic systems have a mutually antagonistic effect upon the striatal cells and a balance is necessary for normal function, alteration of the effect of one system may modify the effects of the other.

Altering the cholinergic input to the striatum can alter the effects of the dopaminergic system on the striatum. This has been demonstrated best in Huntington's chorea.

EFFECTS OF ANTICHOLINERGICS

Patients with Huntington's chorea often present with movements that are similar in appearance to tardive dyskinesias. The pathophysiology of Huntington's chorea is also felt to relate to altered sensitivity of the striatal dopaminergic receptors to dopamine. Patients with Huntington's chorea, when given anticholinergic drugs, show a marked exacerbation of the abnormal involuntary movements (32). If the mechanism of tardive dyskinesias is similar to that in Huntington's chorea, it would be expected that anticholinergic medications could exacerbate the symptomatology in tardive dyskinesias. Institution of anticholinergic regimes for patients with tardive dyskinesia has in fact been found to worsen the abnormal movements (3). It is important to note this because many patients with diseases of the extrapyramidal system are treated with anticholinergics, although the efficacy of anticholinergic therapy has been demonstrated only in parkinsonian syndromes.

Many patients who are on long-term neuroleptic therapy are also given long-term anticholinergic medications in order to reduce the parkinsonian syndrome induced by neuroleptics. While anticholinergics may mask drug-induced parkinsonism, they may also increase the intensity and duration of tardive dyskinesias in any patient who is prone to develop this type of abnormal movements (3). They also worsen chorea in choreatic patients on neuroleptic therapy (32). The attempt to relieve one of the neurological complications of neuroleptic therapy may promote the appearance of another, more severe, longer lasting, and less reversible neurological complication.

Besides prolonging and potentiating tardive dyskinesias, there is some evidence to suggest that anticholinergic drugs may alter the threshold for the appearance of tardive dyskinesias. Anticholinergic agents may not only increase the severity of tardive dyskinesias in patients prone to this type of movement disorder but may also increase the incidence of tardive dyskinesias by altering the threshold for the appearance of these movements. This concept suggests that inhibition of the cholinergic system, which normally antagonizes the dopaminergic system, produces a physiologic state in which the amount of dopamine acting at dopaminergic receptors necessary to produce lingual-facial-buccal dyskinesias is decreased. Because of this, amounts of dopamine too small to induce tardive dyskinesias in a patient not on anticholinergics may well be able to induce them in a patient who is receiving anticholinergics.

This suggests that the incidence of tardive dyskinesias should be greater in patients receiving both neuroleptics and anticholinergics than in patients receiving neuroleptics alone. This appears to be true. Crane (33) has tentatively suggested that adjunctive anticholinergic medication increases the risk of development of tardive dyskinesias. Since most patients receiving long-term neuroleptic therapy do not require anticholinergic drugs (34), it appears that the routine use of these as an adjunct to neuroleptic therapy is not justified.

Biological Psychiatry

BIOLOGICAL PSYCHIATRY has undergone a revolution in the last 20 years. For hundreds of years some psychiatrists have believed that biological factors may cause mental illness, but such theories were at the speculative stage of broad sweeping theoretical statements, nonspecific in nature, that have characterized the prescientific stage of any science. Indeed, these speculations were not so much a scientific theory but more a statement of faith that biological factors did underlie the more serious mental diseases. The discoveries that antipsychotic drugs could help schizophrenic patients, that antidepressant drugs and lithium could help patients with affective disorders, that minor tranquilizers had anti-anxiety properties, and that methadone maintenance was a useful treatment for narcotic addicts have brought chemical means of treatment to a great many psychiatric patients.

Stimulated by these discoveries, the pharmacology of these agents has been rapidly elucidated with a fast and substantial advance in biochemical pharmacology in the last 20 years. Since there are a number of antipsychotic agents that benefit schizophrenia, it is reasonable to speculate that a common mechanism of action shared by all these drugs may be a clue to the biochemistry of schizophrenia. All these agents cause extrapyramidal side effects. Furthermore, it is known that Parkinson's disease is associated with low brain dopamine levels and that antipsychotic drugs block central dopaminergic receptors, implicating dopamine in the drug-produced extrapyramidal side effects.

In this issue of the *Journal*, Snyder reviews this evidence and speculates that dopamine may be involved in schizophrenia. He notes that amphetamine psychosis is very similar to paranoid schizophrenia and that one of the most important biological actions of amphetamine is to release dopamine centrally. Recently, Janowsky and associates (1) showed that a relatively small dose of intravenous methylphenidate, another dopamine releaser, can markedly activate schizophrenia in patients who are actively psychotic, while an identical dose does not have any psychotomimetic effect in normal subjects. That is, schizophrenics respond differently to an identical dose of this drug than normals, another pharmacologic clue implicating dopamine or dopamine-like compounds in the etiology of schizophrenia.

In this issue of the *Journal*, Klawans suggests that tardive dyskinesia may be the result of the increased responsiveness of dopamine receptor sites that occurs as a result of neuroleptic-induced denervation hypersensitivity. In this case, these very serious long-term clinical side effects may be the result of secondary changes involving the same neurotransmitter. Furthermore, in this issue Murphy notes that bipolar patients who respond to dopa ingestion with hypomanic episodes excrete more dopamine than do unipolar patients who do not respond to dopa ingestion with hypomanic episodes. This provides a pharmacological clue toward the biology of mania. Klawans suggests that the presence or absence of dyskinetic movements is controlled by a balance be-

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

tween dopaminergic and cholinergic systems. Janowsky and associates (2) showed that one could markedly reduce manic symptoms through increasing the levels of brain acetylcholine by administering physostigmine. There is much evidence from animal studies that a balance exists between dopaminergic (or noradrenergic) and cholinergic systems, and we have suggested that disorders of affect may involve a balance between cholinergic and adrenergic systems (3). The methodologic studies of Post, Goodwin, Bunney, and their co-workers also add important data about the involvement of serotonin in depression.

The trial of rubidium is also partly motivated by its biological effect on biogenic amine systems or on behavior under the control of biogenic amines in animals. It should be added parenthetically that, since rubidium has such a long half-life, it may be a particularly dangerous drug to study in early clinical drug evaluation. These studies are representative of research that is leading to a rapid increase in our knowledge about the function of neurotransmitters in man and their relationships to underlying psychiatric disease and to drug-produced side effects.

Regardless of how productive theories are, there is no doubt that many of the side effects produced by psychotropic drugs relate to their effects on neurotransmitters. It is important that psychiatrists have some understanding of biochemical pharmacology so that they can have an appreciation of the mechanisms involved in these side effects. Since a full understanding of the concepts of biochemical pharmacology that underlie the research in this issue of the *Journal* is more than that provided in most psychiatric residency training programs, many psychiatrists may find this research somewhat confusing and perplexing. In most residency training programs, psychiatrists are well trained in psychoanalytic theory, historically the first breakthrough of modern psychiatry. Now, with the application not only of psychoanalysis but also of psychological theories and sociological thinking, there are many different disciplines that underlie psychiatry, more than any one man could know. It would follow that a balanced psychiatry department should have experts in most of the various subspecialties of psychiatry who would perform research, train residents in their area of knowledge, and provide a resource for practicing psychiatrists in the community. The papers in this issue illustrate the rapid progress in biological psychiatry. This is but a small part of the rapidly advancing field of biological psychiatry, and it strongly implies that this subspecialty should be among those included in a balanced psychiatric program.

A Year of Change—A Card of Thanks

THIS JANUARY 1973 ISSUE of the *Journal* marks the beginning of volume 130. Volume 129 was made up of only six issues. (We warned about this change in the last several issues; it was made because there appears to be an advantage in having each volume correspond with the calendar year.) We are making this change at the same time that we are instituting changes in format, typography, and page layout. For, as is evident, the *Journal* has changed to a new "A" size. Notice of this was also given in the last issue.

These changes have not been made lightly; in fact, some of us note them with real regret. Despite some production troubles there was a solidity and a certain amount of assurance that came with our green journal, though we sometimes had trouble keeping the green cover green. The *Journal* kept up with the times in editorial content and it will do so in its new dress; the Editorial Board and the staff will see to that.

In the past year the flood of unsolicited manuscripts was the highest ever. Adding these to our annual meeting papers has nearly inundated the *Journal* office. The flow seems to increase exponentially, and we take this as a mark of confidence and approval.

We have had to give up reviewing papers intended for the next annual meeting in advance of the meeting. We did review them early last year, and in some cases it resulted in our reading papers four times, since they were returned from the authors with modifications that had been suggested by reviewers at various stages. This increased the work load so much that we now intend to start the review process only after the papers have been presented at the annual meeting.

Each manuscript we receive is seen by one or more capable reviewers before the final decision is made to accept, modify, or reject. That we miss sometimes is understandable, but the decision is never made hastily; in fact, we agonize over some of the papers a great deal before the final decision is reached.

It is readily understandable that to make proper decisions the Editor must seek help from knowledgeable colleagues, although in the end the final decision is his. The calls made upon these colleagues are often time-consuming and may be a burden to the person asked to help. Unfortunately, the *Journal* is not in a position to repay these colleagues as they should be repaid. Therefore the least we can do is to publicly acknowledge our indebtedness to them. This is usually done in the January issue at the time that the Editor and staff convey to them and all of the *Journal*'s readers their best wishes for health and happiness in the year ahead.

This year our good wishes are even more poignant, for as this is written the nation is upset and in an unhappy, disbelieving mood. We hope that the New Year will see us at peace so that we can solve some of our own home-grown problems. A number of these problems affect our specialty. More than ever we are a part of the community, and there are marked changes ahead for our own discipline and all of medical practice.

The names of those colleagues and friends whom we have called upon for help of some sort from November 1, 1971, to November 1, 1972, are listed below.

Depression in the Menopause

BY GEORGE WINOKUR, M.D.

The author studied 71 women who had an affective disorder either before or after the menopause to determine if they were at greater risk for depression during the menopause than during other times of the life span. The difference was not significant: there was a 7.1 percent risk of developing an affective disorder during the menopause and a six percent risk during other times.

CLINICIANS have long been interested in the impact of the menopause. The concept of involutional melancholia is based on the idea that the menopause has significant psychological and physiological effects that lead to a serious depression in predisposed individuals. However, it is possible that depressive episodes around the time of the menopause may simply be chance occurrences. Such would be the case if the risk for depression were increased in the ages during which the menopause occurred without the menopause itself contributing to the development of the depression. It is possible that the relationship of menopause to depression is simply fortuitous.

Slater has calculated the risk for a first attack of manic-depressive disease during the life span (1). About 20 percent of the first attacks occur in each of the three decades between 30 and 59 years of age. Since the decades between ages 40 and 59 are the time when a great number of menopausal periods occur, as well as 40 percent of the first episodes of manic-depressive illness, it is not surprising that depression and the menopause have been associated by the physician. In this paper I have attempted to determine if menopause increases the risk of depression in patients who have had an affective episode independent of the menopausal state.

METHOD

Of patients with an affective disorder, 76 consecutive admissions were chosen for the study, using the criteria of Cassidy and associates (2). The presence of several symptoms such as insomnia, anorexia, psychomotor retardation, tiredness, and difficulty in concentrating were needed for the diagnosis. This illness had to be superimposed on adequate adult functioning, and no other psychiatric or medical diagnosis could have seemed probable. These patients could have been diagnosed in the categories of manic-depressive illness, psychotic depressive reaction, and involutional melancholia. Five women who had an affective disorder associated with a postpartum state were eliminated, leaving 71 consecutive female admissions with a diagnosis of affective disorder. Twenty-eight women in the study had passed the menopause, which was defined as lasting three years following the age the patient gave for its onset.

An episode of illness in the women was expressed in terms of a period of time; a subject could have had only one episode a year.

Two formulas were used. For the entire group of 71 women the risk for occurrence of an episode of illness equaled the number of episodes (defined as a period of time) divided by the total numbers of years at risk for the population. The risk was expressed as a percentage of the years at risk that were associated with an affective episode.

This computation was then compared with the risk for the occurrence of an episode of illness in association with a specific event (in this case, menopause). This equaled the number of episodes (defined as a period of time associated with the event) divided by the total number of years at risk for the event.

RESULTS

In the group of 71 patients there were 125 episodes of psychiatric illness and 2,095 years of risk. Using the number of episodes as the numerator and the years at risk as the denominator, it was found that six percent of the years at risk were associated with a psychiatric illness. To obtain the number of years at risk each patient was dealt with individually, and the computation was made for the number of years at risk between ages 20 and 80. The greatest number of years that a person could be at risk would be 60, and the least would be five if the person was

Dr. Winokur is Professor and Head, Department of Psychiatry, University of Iowa College of Medicine, Iowa City, Iowa 52240.

This work was supported in part by Public Health Service grants MH-11396 and MH-05911 from the National Institute of Mental Health.

older than 20. The computation of the period at risk for these 71 patients was described in a previous paper (3).

Of the 28 women in the study who had passed the menopause, all reported expected menstrual changes. During the menopause 21 (75 percent) reported nervousness; 10 (36 percent), depression; 10 (36 percent), insomnia; 18 (64 percent), hot flashes; 9 (32 percent), fatigue; 8 (29 percent), palpitations; and 2 (7 percent), difficulty in concentration and thinking. Since these symptoms are similar to those which patients suffering from affective disorder complain of, it was necessary to define an affective episode that occurred during the menopause as one in which there had been a hospitalization within three years of the age the patient gave for the occurrence of the menopause. Six of the 28 patients reported that such an association took place. Using the formula cited before: rate $= \frac{6}{28 \times 3}$ = 7.1 percent. Therefore, 7.1 percent of the years at risk were associated with a hospitalization for an affective episode. This percentage is not significantly different from the rate for the total group of 71 female patients (6 percent).

Nine patients had an illness prior to menopause. Of these, seven were free of illness that required hospitalization during the three-year period of risk for menopause, while two were not.

DISCUSSION

From the current data menopause does not seem to be an important factor in precipitating an episode of affective disorder. That it has been so considered may well be the result of the chance association of menopause and affective disorder and of a third factor, age.

There are possible sources of error in the kind of workup that is presented here. An episode of illness that occurred in the menopausal period had to be defined as contingent upon a hospitalization, whereas during other times of the risk period, an episode was defined as a set of symptoms associated with some social incapacity. This partial change in definition of an affective episode could obscure some differences between the ordinary period of risk and the period of risk during the menopause.

The majority of patients in this study were depressive; few had had any mania. The patients were not, however, divided into two groups—those with mania and those without mania. It would be of interest to determine the effect of menopause on the two groups, i.e., patients who have depression only and patients who have mania and depression. The separation between unipolar and bipolar affective psychoses seems to be a viable one, both clinically and genetically; it would be useful to evaluate possible precipitants, such as the menopause, separately for the two groups (4).

Finally, from the data presented here there seems to be little value in looking specifically at the menopausal state for clues to the etiology of ordinary affective disorder in which hormonal changes have been suggested as etiological factors. To some extent this has been a result of the belief that affective disorders are more likely to occur during menopausal states. This does not appear to be true, and one might expect to find no significant leads in such occurrences that would promote further understanding of affective disorder. The numbers in the study reported here are, however, relatively small, and another study might be in order, particularly one that divided the patients with affective disorders into those with and those without mania.

The Polygraph in a Psychiatric Setting

BY STANLEY ABRAMS, PH.D.

The author discusses the use and validity of the polygraph in a psychiatric setting. By setting up a hierarchy of stress words—some of which are supposed to elicit an emotional response and some of which are not—the psychiatrist can determine specific stress areas by means of the patient's physiological reactions.

THE POLYGRAPH has often been employed in law enforcement, business, and government, but it has been used only rarely in psychiatric settings. Since this instrument does not measure lies but rather emotional responses through physiologic reactions, it could be assumed to be of value in this realm.

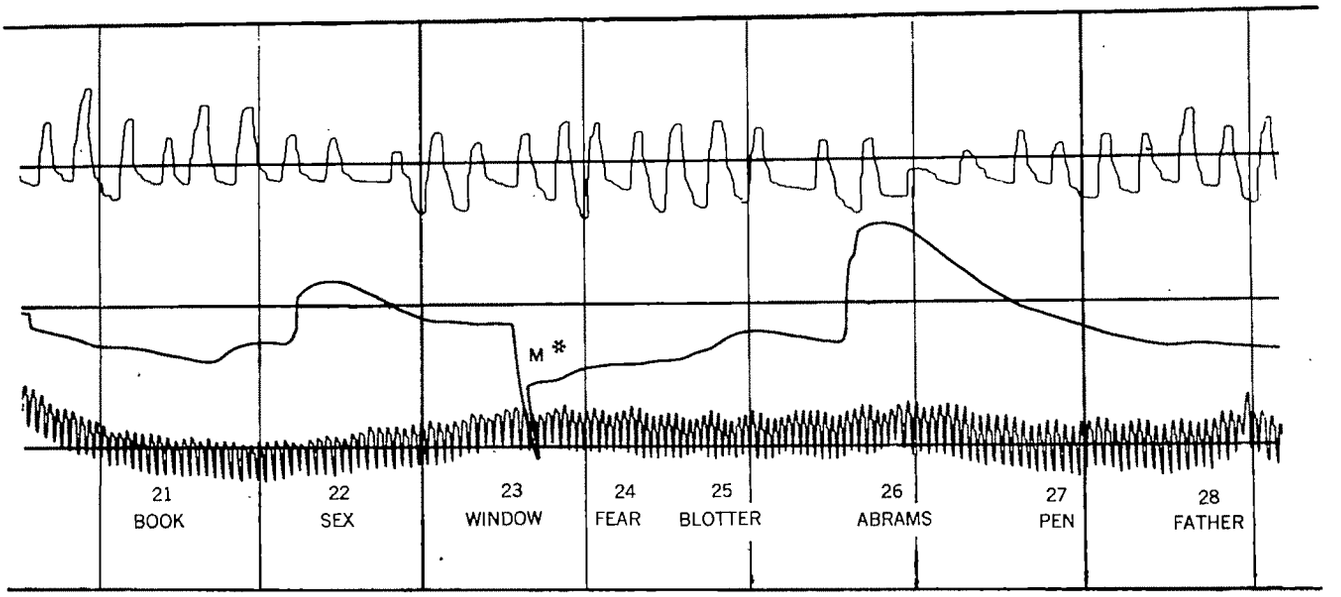
The effectiveness of the polygraph has been amply demonstrated in the literature through both laboratory research (1, 2) and the reports of polygraph experts (3–5). In the former, 70 to 100 percent accuracy has been indicated, while polygraphers themselves report 90 to 100 percent validity. A number of criticisms have been leveled against this technique, with the foremost currently being directed toward the right to privacy and the right to avoid self-incrimination. With this as a basis many unions have strongly backed any legislation against the use of the polygraph in business and in government agencies, and because of this, use of this instrument has been reduced to some extent in these areas.

A second objection to the polygraph is related to the training, education, and ethics of the examiners. Most states do not have licensure laws, not due to any lack of activity of the polygraphers but because special interest groups have blocked progress in this direction. Therefore there is no legal reason why anyone cannot buy this equipment and sell his services as an expert in the field.

The polygraphers who have been trained are generally law enforcement officers who have taken a concentrated course that often includes an internship. However, this specialized training is not considered adequate by some since many of these examiners do not have a college degree. The American Polygraph Association is attempting to have licensing laws passed, to set up qualifications for both polygraph experts and polygraph schools, and to develop ethical standards for the examiners.

The final criticism of the polygraph is related to its so-called lack of scientific acceptance. Questions regarding the validity and reliability of the polygraph are difficult to answer because the investigation of this approach is handicapped by weaknesses inherent in the research procedure itself. Experimental findings, even those emerging from a mock crime, cannot be fully accepted as meaningful because the emotions associated with detection in such a case are simply not comparable to the fear of detection operant in an actual crime situation. Trovillo (6) pointed out that "drastic stress" is not part of the experimental situation, for, in contrast to a criminal suspect, the laboratory subject has little to lose. Compare, for example, the penalty of detection for a volunteer subject with that of a murder suspect who wagers his life that he can "beat" the polygrapher. Inevitably the level of validity attained from a hypothetical situation is not comparable to that attained from an actual crime situation.

While this is an obvious weakness that is part of the experimental paradigm, field research also has its failings. There is no way of adequately controlling the examinations given in a typical law enforcement situation. Moreover, verification of the results is never obtained in many polygraph tests. However, when polygraph charts *are* verified, high validity is generally attained (7).



From these statements one can readily see that it is almost impossible to develop an experimental design that will adequately test the validity of the polygraph approach. What is known, however, is that the polygraph is of great value in law enforcement work. It has been a definite aid in recovering losses, in obtaining confessions, and in demonstrating innocence. In some manner demonstrating innocence seems to have been underplayed, but this, according to many attorneys and police officers, is one of the main functions of the instrument.

The polygraph has also been employed by the government to reduce security risks. It has been used not only with those already employed, but with job applicants as well, since it is often more economical and expedient to clarify areas of doubt with the polygraph. Information on medical conditions, use of drugs, or past criminal activity is often more easily obtained with the polygraph than through either interviews or psychometric techniques. Business and government conduct an estimated 200,000 to 300,000 of these tests annually (8).

In the business field polygraphers are often called in to determine who is responsible for financial or material losses, but there is less awareness of its utilization as a preventive measure to reduce theft. Employees may be examined periodically, and the knowledge that these ex-

aminations will be carried out results in great savings. The unions, as indicated earlier, have objected, claiming that such tests are an infringement on civil liberties. This objection may be well founded; however, it must be pointed out that these business savings are passed on for the benefit of all consumers. The moral question is: Whose rights are at stake, the individual's or society's, the employee's or the employer's?

A number of different manufacturers produce polygraph equipment, but basically the equipment is the same. Most of the equipment used consists of measures of heartbeat amplitude and rate, changes in blood pressure, breathing pattern and rate, and galvanic stimulus response. Basically, any change in these areas is indicative of a change in affective response and, to some degree, it is expected that the greater the emotional reaction, the greater the change in physiologic response. It can be assumed then that a hierarchy of responses can be demonstrated that might be of value in determining areas of significance. This would allow a therapist to test his thinking regarding the dynamics of a patient's problem and could possibly open up new areas of difficulty.

METHOD

In an attempt to determine if such an approach might be of value, 20 patients who had been in treatment were examined with the polygraph. Each patient was given a total of 40 stimulus words alternating between assumed neutral words and words that were thought to be relevant to each individual. The series of words varied with each person. The neutral words served as a basis of comparison with the relevant words and helped to bring each patient's emotional level back down after he had heard a relevant word. An approximate 15-second pause after each word allowed sufficient time to obtain a meaningful tracing in all the physiologic areas. The subjects were instructed to sit perfectly still with their eyes closed and to make no verbal response to the words presented. A Keeler 6308 three-channel polygraph was used.

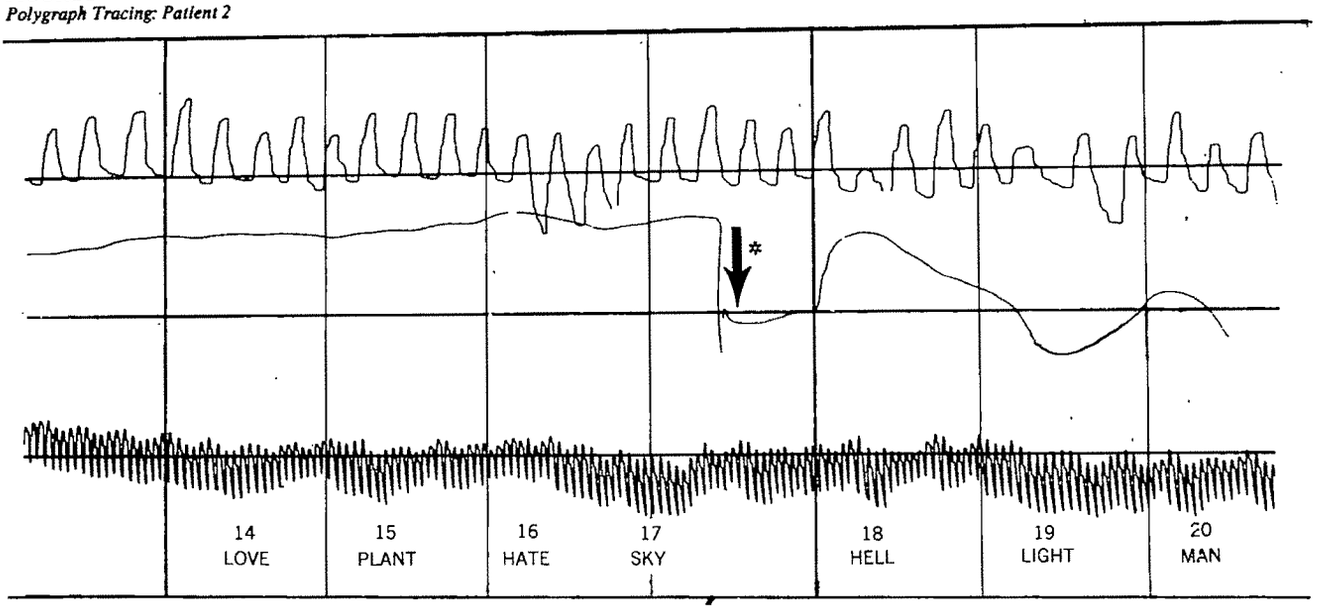

Figure 1 shows a typical set of polygraph tracings. Respiration is at the top, galvanic skin response (GSR) in the center, and a combination of rate of heartbeat and blood pressure at the bottom. The GSR pen is longer than the other two pens so as not to become bound up with them. This results in the GSR tracings being seven seconds behind the other two. The regularly placed vertical lines are 15 seconds apart, which allows the reader to judge how far behind the GSR response is in comparison with the other tracings.

The numbers indicate the specific stimulus words. Any major change in the tracings points up an emotional response, but again, it is not possible to determine which emotional response or combination of responses is elicited. There are about 30 different changes in the tracings that could be indicative of an affective reaction.

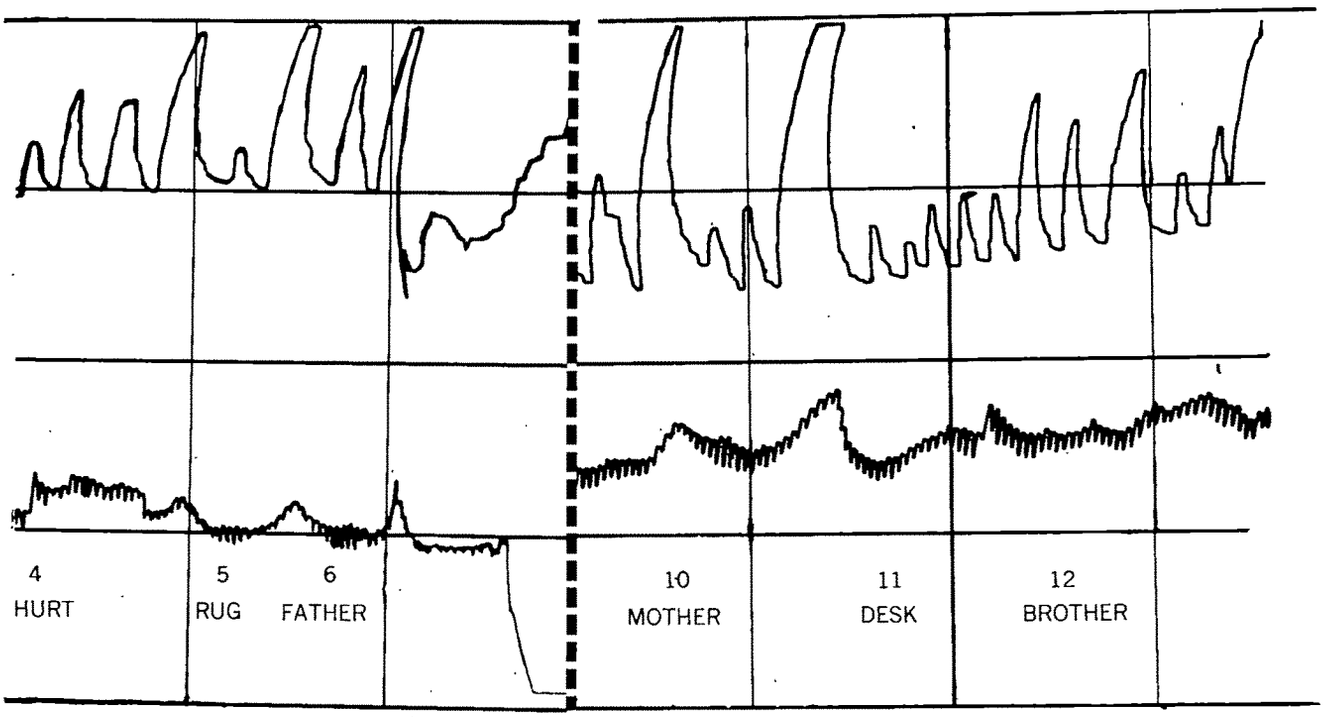
DISCUSSION

In figure 1, stimulus word 23, "window," proved to be a poorly chosen neutral word. Instead of the expected lack of response, the patient showed a definite reaction. He later admitted that he had considered committing suicide by jumping out of a window. Note that the response on GSR to the word "window" was greater than to the preceding word, "sex." While there is a response to

FIGURE 2
Polygraph Tracing: Patient 2

*Adjustment of GSR down to center line.

"sex," it does not compare with the GSR response to "window." The respiration response to words 22 and 23 show suppression of breathing, which is another indication of an emotional reaction. Word 26 is the therapist's name. It resulted in a very large GSR response, a slight rise in blood pressure, and suppression of breathing. This is an expected response, registered in all of the physiologic areas, for a patient has many ambivalent feelings toward the therapist. In contrast, the patient reacted relatively little to neutral word 27, "pen." Comparing these words with each other, some insight can be gained as to which ones are more pertinent to the patient.



In figure 2 another patient with many thoroughly ingrained moralistic notions gave a large response to word 18, "hell." The diastolic blood pressure increased and the systolic decreased, resulting in a reduced amplitude, which is perhaps one of the best indications of an emotional reaction manifesting itself in terms of blood pressure. The GSR shows a short and sudden increase; at the same time the patient took a sudden short breath such that this stimulus can easily be interpreted as a definite area of difficulty. Again, contrast this reaction to those elicited by word 19, "light" and word 20, "man." Each of these caused a response, but they obviously do not compare with the highly loaded word "hell." Comparing one response with another, it can easily be seen which areas are of most stress to the patient.

The subjects frequently reported surprise at substantial polygraph changes showing great responses to specific stimulus words for which no reaction had been anticipated. It was assumed, therefore, that the feelings associated with these particular words were at an unconscious level. If this is true, then in contrast to earlier assumptions (9), the polygraph is sufficiently sensitive to detect physiologic responses to repressed material. Some corroboration for this is found in a study by Weinstein and associates (10). They demonstrated that while hypnosis could cause amnesia regarding a mock crime and reduce the feelings related to it, the process was not so complete as to remove all of the physiologic responses. It can be assumed from both of these studies that the polygraph can detect emotional reactions to unconscious stimuli but not so readily as it can detect information and affect available to the conscious mind.

A response to assumed neutral words, such as "window," in which the stimulus word had definite significance to the patient at a conscious level, occurs in a lie detection situation as well. While this occurrence could distort the results, it is unlikely, since polygraph examiners typically question a subject when there is a large reaction to a nonpertinent item. Should this reaction occur by sheer chance during a question related to the crime, it would appear as a deceptive response. Such a response would not create a problem, however, since the polygrapher would not make a judgment of deception on the basis of only one question.

When a patient gave a high response to a word that was neutral or for which he did not expect a response, it opened the door to new material that could be dealt with in therapy. Information that undoubtedly would have come out in time was treated more rapidly, with the patients themselves becoming very involved. Each individual went over his tracings with the examiner and took the results almost as a homework assignment in an attempt to understand the reasons for his reactions. Perhaps he dealt with this information only on an intellectual level, but at this point such patient involvement appears to be a valuable aid in the treatment process. Much the same procedure could be employed using some physiologic feedback system associated with Wolpe's ap-

FIGURE 3
Polygraph Tracing: Patient 3

proach of desensitizing a patient with a phobic reaction.

While the majority of patients responded as expected and while some reacted strongly when it was not anticipated, others gave no response to stimulus words that we assumed would elicit one. It was believed that the individuals who did not respond had overemphasized a particular area in therapy to avoid talking about their underlying problem. The more they could talk in this vein, the longer they could avoid the more threatening and significant areas.

It was of interest to note that in a number of instances the response to siblings was greater than to either parent. This corroborated the patients' descriptions of the constant pressure they were under as children from the degrading, haranguing dominance of older siblings. This certainly had as much of a debilitating effect as any poor parent-child relationship. In fact, I feel that the effect of siblings on one another is underestimated and that too much of the credit or blame is given to parents. Note, for example, in figure 3 the difference between the reactions to stimulus words "brother" and "father." The response to the word "brother" is distorted because at this point the patient suddenly began to weep.

CONCLUSIONS

In general the polygraph was found to be of value. It uncovered specific problem areas and allowed the development of a hierarchy of stress words that was useful later in the treatment process. Obviously, it is not possible to use this device as a diagnostic aid, but it does graphically demonstrate how an individual's physiology can present worthwhile information to the therapist. This, of course, is well known and has been employed as part of diagnostic and treatment procedures, as the therapist notes the blushing, perspiring, or trembling of a patient. In addition, the polygraph provides a continuous and measurable indication of a patient's emotional reactions to pertinent stress areas. Because of this, it could be an effective research tool in evaluating desensitization of stress areas, in comparing the therapist's opinions with the physiologic responses of the patients, and in establishing a hierarchy of affective levels.

An Episode of Acute, Self-Limiting Depersonalization Following a First Session of Hypnosis

BY ELLIOT N. WINEBURG, M.D., AND NORMAN STRAKER, M.D.

A stable subject with a negative medical and psychiatric history developed a self-limited episode of depersonalization after an uneventful hypnotic session. Nothing in the subsequent psychiatric examination, except conscious sexual fantasies during the experience, could have predicted this reaction. The authors believe that all hypnotic subjects should be observed after hypnotic treatment.

AN INTEGRAL PART of the course on hypnosis for psychiatrists at our hospital has been live demonstrations of trance states in normal subjects. Following our usual procedure, one of us announced to a group of hospital employees that volunteer subjects were needed. A reward to the participant was promised in the form of help in eliminating some unwanted habit, such as smoking. The recruiting psychiatrist was alerted to accept only persons who met the following strict criteria: 1) sound ego structure, 2) not prepsychotic, and 3) not currently or previously under psychiatric treatment.

With the encouragement that she could control her smoking habit, a stable young woman volunteered. Long known as a well-adjusted co-worker, she was instructed to come to the hypnosis course the following week. On entering the classroom, the subject showed only slight (and not unusual) anxiety at the beginning of an uneventful hypnosis session. Before the session she announced that she would prefer to have help with her moderate weight problem instead of her smoking. The director of the course agreed to this change of "therapeutic goal," and the demonstration in hypnosis began.

HYPNOTIC PROCEDURE

The subject was given simple commands at the prehypnotic stage (e.g., "Sit here.... Move your chair.... Step out of your shoes...."). Induction was accomplished by Erickson's finger levitation technique (1): "An imaginary string is attached to your finger and is tied to an imaginary balloon which is lifting your finger." The subject's finger rose promptly and was followed by her arm. Deepening the trance was brought on through a slow counting from one to 20, with suggestions that the subject was sinking into a state of total relaxation. Her breathing became slow and deep; the tone of her facial muscles indicated that she had reached a good state of relaxation. Challenges were also successfully met: eyelid catalepsy—"Your eyes are closed, they cannot be opened..."; hand paralysis—"Your hand and arm remain on the chair; you cannot raise them..."; and arm catatonia—"Your upraised arm is tight and stiff.... You cannot bend it...." Finally glove anesthesia with capillary contraction were produced. This allowed the patient to withstand the passage of a number 18-gage intramuscular needle through the skin at the dorsum of the hand without her evidencing pain or withdrawal. Only one drop of blood appeared. The subject was allowed to witness the presence of the long needle before it was withdrawn from the back of her hand. Until this point all suggestions were reversed after each challenge. The patient had reached the stage of light trance, score 11 on the Davis-Husband system (2).

In this relaxed state, the subject was told that she could overcome her excessive eating habits, that at meals her "appetite center" would be numbed, that she would be satiated after the intake of a standard low-calorie fare, and that between-meal-hunger would be stilled. She was also told that after awakening, she would feel alert, rested, optimistic about losing weight, and "perfectly normal." At the count of ten she was dehypnotized. Her eyes opened promptly and, stating that she felt well, she left the room.

REACTION AFTER HYPNOSIS

The subject, as she later described the episode, felt sleepy on returning directly to hospital duty. Although she was given several cups of black coffee by co-workers,

The authors are with the Department of Psychiatry, Mount Sinai School of Medicine, New York, N.Y., where Dr. Wineburg is Associate Psychiatrist and Dr. Straker is Minnie Kastor Research Fellow. she experienced difficulty in functioning. She became increasingly anxious as obsessive recall of the hypnotizing doctor's voice filled her thoughts. Fears that she might lose control seized her, and she further worried that the repetitive recollections of the hypnotic sessions were hallucinations.

Co-workers (none of whom was a physician) later described her behavior in subjective terms. A nurse reported: "Oh, she was acting goofy; she was just hypnotized." Considerably more concern was evidenced by her supervisor, who noted "aimless body movement" and an unusual "shifting of gaze." "She looked around the room, not at any subject." Some abulia was present, and the supervisor sensed that she had to make immediate decisions for the subject. The subject was then escorted into a taxicab and told to rest at home the next day instead of reporting to work. After the subject was dispatched to her apartment, the supervisor learned of the hypnosis from another employee and immediately phoned the subject; the latter was awakened and again became anxious after the supervisor extracted a detailed description of the hypnotic session.

Although encouraged to arouse her roommates, the subject returned to bed and slept well until the next morning. She then impulsively decided to go to her parents' home for the weekend—a trip of more than 100 miles one way. At home the anxiety lessened, the obsessional playback of the hypnotic suggestions waned, and she no longer feared she might lose control. Only one unusual event occurred during this time: She accidentally spilled hot syrup, causing a burn on the same hand that had originally been anesthetized under hypnosis. Of course the anesthesia had been removed, and the patient experienced pain following the trauma.

The hypnosis had taken place on a Thursday afternoon. Monday morning the subject returned to work and has remained symptom free since. Her eating habits have responded to the posthypnotic suggestions; she does not "snack" between meals and keeps to a low-calorie diet. She lost 13 pounds in the first seven weeks.

PSYCHIATRIC EXAMINATION

The subject was a 26-year-old paraprofessional who had served with one medical unit since graduating five years previously. She had an excellent work record.

She could not date the origin of her problems with obesity, saying she had been heavy like her mother for as long as she could remember. She had tried various diets and had with great effort lost over 50 pounds, only to regain the weight later. Her eating pattern included a light breakfast, lunch, and supper. Excesses occurred during the evening work shift, when she was continually snacking, and before bed. She noted an increased intake during mildly depressive moods, which were infrequent and did not interfere with routine functions. She had never had any anorexia.

Her medical history was essentially negative. At the time of college graduation she had tension headaches.

She has had many social relationships outside of work, but she claimed she has found it difficult to be herself, especially at parties, where she has felt anxious and self-conscious. She thinks of having children in the future and looks forward to enjoying motherhood; she is less secure about her role as a wife.

A mental status examination revealed a mildly obese young woman who was pleased to be given the opportunity to talk about herself. Although she was slightly anxious at the beginning of the interview and was somewhat guarded, she relaxed later. Candidly, she admitted some concern about her failure to have more intense relationships with the opposite sex. During the interview she showed no signs of depression or any evidence of psychosis. She was bright, very conscientious, and somewhat inhibited.

Two particularly important factors stood out: the subject's wish to lose control and her fear of this. Further inquiry into her fantasies about the hypnotic experience revealed that the subject thought she might say and do things she would not ordinarily do, and that she would not remember any of this afterward. Her knowledge of hypnosis was from a movie, "Divorce American Style," in which a woman was told to be a coffeepot and an exotic dancer. Fearing she would be given similar orders, our subject entered the session certain she could not be hypnotized. Initially the subject "played along" but became quite anxious as well as "excited" when she could not bend her arm as instructed. She then felt she was under the doctor's control. She wondered, "Does the superego change?" Under questioning, she confessed to feeling sexually excited by some fantasies she had while hypnotized but chose not to reveal them.

During the depersonalization episode, she was embarrassed when talking to her supervisor; she feared she would be judged "crazy."

DISCUSSION

We failed to pinpoint factors in the subject's medical history or psychiatric interview that would have forecast her brief episode of depersonalization. Her work record also offered no clue to her short-lived psychopathologic reaction. Only a retrospective analysis of her fantasies about the hypnotic session yielded some understanding of her reaction. A fear of losing control with a possibility of fulfilling some unconscious (sexual?) wishes set off the inappropriate defense mechanism that was clinically described as depersonalization. The aloofness, fatigue, obsessive recall of the hypnotic monologue, and brief withdrawal from work and colleagues served to "protect" the subject from acting out her forbidden (and to us unknown) fantasies.

We have considered the possible threat of weight reduction and the patient's use of obesity as a permanent defense structure. However, the limited psychiatric interview provided insufficient evidence to confirm this hypothesis, and projective testing or extensive psychoanalysis could not be obtained.

CONCLUSIONS

We observed a brief episode of decompensation in an apparently normal subject following hypnosis. The period of depersonalization described here lasted only a few hours and was clearly self-limiting, with a complete return to the premorbid stage. A subsequent inquiry into her fantasies associated with hypnosis revealed expectations of a sexual experience while under the trance. In the posthypnotic phase the forbidden impulses yielded to defense mechanisms producing the state of depersonalization.

Our clinical experience reiterates the principle that hypnosis is a serious medical procedure and requires adequate safeguards (3). We specifically recommend: 1) a follow-up observation of the patient and an opportunity for the patient or his family to contact the hypnotizing physician if needed; 2) an investigation of the patient's expectations of hypnosis, real or fantasied, which is essential to the mandatory pretreatment examination; and 3) an explanation of the true nature of hypnosis, which may serve as an affective prophylaxis to episodes such as the one we have described.

Usual and Unusual Agranulocytosis During Neuroleptic Therapy

BY J.V. ANANTH, M.D., D.P.M., J.V. VALLES, M.D., AND J.P. WHITELAW, M.D.

Agranulocytosis, an uncommon side effect of phenothiazine treatment, usually occurs within the first three months of such treatment and remits after the substitution of another neuroleptic. The authors report one patient in whom the illness took its usual course and two in whom it did not. Of these two, one patient demonstrated agranulocytosis only after years of phenothiazine therapy and the other showed agranulocytic reactions to various neuroleptics.

THERE ARE many reports of agranulocytosis associated with the use of various phenothiazine derivatives. Both drug dosage and the duration of administration are considered to be important factors in producing this type of agranulocytosis (1). A third factor, individual susceptibility, is also considered to be a significant contributor to its incidence. While agranulocytosis has been estimated to occur in one out of every 10,000 persons treated with phenothiazines (2), leukopenic and granulocytopenic reactions have been more frequent. Pisciotta (3) found transient, moderate, and spontaneously reversible leukopenia in about 2,000 of 6,200 patients receiving phenothiazine therapy. Agranulocytic reactions, however, have been infrequent.

The agranulocytosis usually occurs within the first three months of therapy and often is evident after the first ten days (1). However, agranulocytosis can develop after prolonged phenothiazine administration (4–6). Methods used to prevent the recurrence of blood dyscrasia in the presence of unrelenting psychopathology include changing the incriminated phenothiazine to a congener (usually a piperazine derivative) (7), and substituting one of the other neuroleptic subgroups, i.e., a butyrophenone (8) or a thioxanthene. While these measures are often met with success, sometimes agranulocytosis recurs no matter what antipsychotic drug is used.

In this report three case histories are presented that illustrate the usual and unusual courses of agranulocytosis following the administration of a phenothiazine. The first case report illustrates the common experience with agranulocytosis; the second case illustrates unusual agranulocytosis with subsequent tolerance to a second neuroleptic drug; and the third case demonstrates recurrent agranulocytosis or leukopenia after the administration of three different neuroleptic drugs.

CASE REPORTS

Case 1. A 59-year-old man with a diagnosis of psychotic de-

pression was admitted to Douglas Hospital in Montreal on July 19, 1971, for treatment of depression and psychomotor retardation. The same day 400 mg. of methotrimeprazine a day and 75 mg. of imipramine a day were prescribed. Since the patient's symptoms improved, the dose of methotrimeprazine was reduced to 200 mg. a day on August 9, 100 mg. a day on August 16, and 50 mg. a day on August 27. The imipramine was discontinued on August 16. On August 23, the patient had a temperature of 101F, which responded promptly to the administration of 500,000 units of penicillin given four times daily for three days. However, his temperature in the morning continued to spike to 99F. By September 3, he was still bedridden, and rales were heard over the base of the right lung. For these reasons methotrimeprazine was discontinued.

On September 7, his white blood cell count (WBC) was 2,135 cells per cu. mm., with 3 percent neutrophiles, 90 percent lymphocytes, and 7 percent monocytes, compared with his predrug WBC of 6,970 on August 19, 1971. Toxic granulation was observed on September 8, when the total WBC was 2,020 cells per cu. mm., with 4 percent neutrophiles, 89 percent lymphocytes, and 7 percent monocytes. The hemoglobin was 10.6 gm./100 ml., the hematocrit was 33 percent, and the sedimentation rate was 29 mm./min. The next day, September 9, the total WBC had risen to 3,349 cells per cu. mm., with 26 percent neutrophiles. From then on the WBC rose steadily and reached the normal range in four days.

Case 2. A 39-year-old woman was admitted to Douglas Hospital in 1946 with a diagnosis of mental deficiency with psychosis. The patient was started on 400 mg. of chlorpromazine a day on February 21, 1955. Over the years this dose was increased to 1,600 mg. a day. Between 1955 and 1967 the patient received reserpine, luminal sodium, prochlorperazine, and perphenazine. On March 5, 1967, she was started on 800 mg. of methotrimeprazine, 6 mg. of trihexyphenidyl, and 100 mg. of luminal sodium daily. This regimen was continued until January 3, 1969, when the patient developed a fever and sore throat, accompanied by a WBC of 800 cells per cu. mm., all of which were lymphocytes. The hematrocrit was 30 percent, with a hemoglobin value of 10 mg./100 mg. The bone marrow was hypocellular in the granular series with normal erythrocyte and megakaryocyte numbers.

Since 1956, her WBC had never fallen below 4,500 cells per cu. mm. The patient was treated with 2 gm. of cloxacillin given intravenously every four hours and 500 mg. of kanamycin given intramuscularly every eight hours for five days. On January 7, 1969, her WBC was 1,700 cells per cu. mm., with 157 juvenile neutrophiles. In two weeks the patient's condition had improved, and she was returned from the medical service to her psychiatric bed. She was kept free of medication until September 22, 1969, when she was started on 10 mg. of thiothixene a day because of aggressive behavior. At this time her WBC was 5,000 cells per cu. mm., with 48 percent neutrophiles. Since her symptoms did not improve; the thiothixene was increased to 60 mg. a day with adequate therapeutic response and without hematological side effects.

Case 3. A 54-year-old woman was admitted to Douglas Hospital on March 10, 1971, for depression, agitation, and persecutory delusions. A diagnosis was made of schizophrenia, paranoid type. Prior to this the patient had been admitted to Jewish General Hospital on December 5, 1970, for similar complaints. She had received 200 mg. of chlorpromazine a day and 125 mg. of trimipramine a day along with electroconvulsive therapy. On December 27, 1970, she developed a persistent fever of 102F along with confusion and weakness. The only abnormal finding noted on physical examination was diminished air entry in the left lung base associated with fine rales. Her WBC of 4,100 cells per cu. mm. on admission dropped to 1,200 cells per cu. mm. by December 31, 1970. Of these 1,200 cells, 59 percent were neutrophiles; 38 percent, lymphocytes; and 3 percent, monocytes. The hemoglobin was 9.5 gm./100 ml. One day after her medication was discontinued her WBC rose to 2,800 cells per cu. mm. By January 6, 1971, it had risen to 8,900 cells per cu. mm. Bone marrow aspirates revealed "recovery stage of agranulocytosis with myeloid arrest." Blood and urine cultures were negative. Chest X rays revealed a "poorly defined left hemi-diaphragm associated with loss of the left costophrenic angle indicating the presence of pleural effusion"; all other investigations were normal. The patient was treated with ampicillin and gentamycin. She was afebrile 48 hours later, and by January 12, 1971, she was fit enough to be discharged to her home. While she was in the medical ward, administration of haloperidol produced a leukopenic reaction necessitating withdrawal of medication.

On admission to Douglas Hospital in March 1971, the patient had a total WBC of 3,150 cells per cu. mm., with 63 percent neutrophiles, 35 percent lymphocytes, and 2 percent eosinophils. Thiothixene was given at a dose of 15 mg. a day and was gradually increased to 30 mg. a day by April 21, 1971. Her blood was monitored twice weekly. By August 4, the WBC had reduced to 2,630 cells per cu. mm., with 60 percent neutrophiles and 36 percent lymphocytes. All medications were consequently withheld. Shortly after the WBC increased to 4,080 cells per cu. mm. Since her psychopathology failed to remit, the patient was given 8 mg. of perphenazine a day, beginning on October 16, 1971, and increasing to 16 mg. a day by October 21. The WBC decreased again to 2,650 cells per cu. mm., with 57 percent neutrophiles, 33 percent lymphocytes, 4 percent eosinophils, and 6 percent monocytes. Immediately after perphenazine was discontinued her WBC increased.

DISCUSSION

It is usual for a mild, reversible agranulocytosis to develop within the first three months of phenothiazine administration. The bone marrow during this period of agranulocytosis appears to be aplastic. The usual full recovery indicates that the marrow stem has been spared by the drug. Because the average life span of healthy erythrocytes is 120 days and because agranulocytosis develops acutely, anemia does not accompany the leukopenia. The first case report provides an example of this typical reaction.

It is unusual for agranulocytosis to manifest itself after years of phenothiazine treatment. In such cases there is always the possibility that the reaction has been associated with viral disease, physical illness, or an increase in the medication dosage. In the second patient the dosage of methotrimeprazine had been the same for about two years prior to the reaction. This indicates that an increase in the dosage was not the etiological factor. Even after several years of treatment, the leukopenia was unassociated with anemia—an indication of the acute onset and the absence of a slower disease process. The patient did not suffer a drug reaction when she was given thiothixene.

Usually changing the phenothiazine or substituting another class of neuroleptic will prevent recurrence of an agranulocytic reaction. In the third patient, neither the

phenothiazine derivative, perphenazine, nor other neuroleptics, thiothixene or haloperidol, were useful in preventing severe leukopenic reactions. This patient may have a less efficient mechanism of DNA synthesis. It has been shown that some chlorpromazine-sensitive patients have a defect in incorporating thymidine phosphate into DNA (9). Thus, there is a strong suggestion that this particular case of agranulocytosis was caused by the administration of a phenothiazine to a susceptible patient.

These three case reports show not only that agranulocytosis may occur within the first three months of therapy, but also that severe leukopenic reactions may suddenly occur even after years of treatment with the same phenothiazine. Furthermore, some patients appear to be susceptible to acquiring the agranulocytic reaction from all of the neuroleptic preparations. Therefore, caution must be exercised when substituting an antipsychotic medication to prevent agranulocytosis that has developed through the use of another drug.

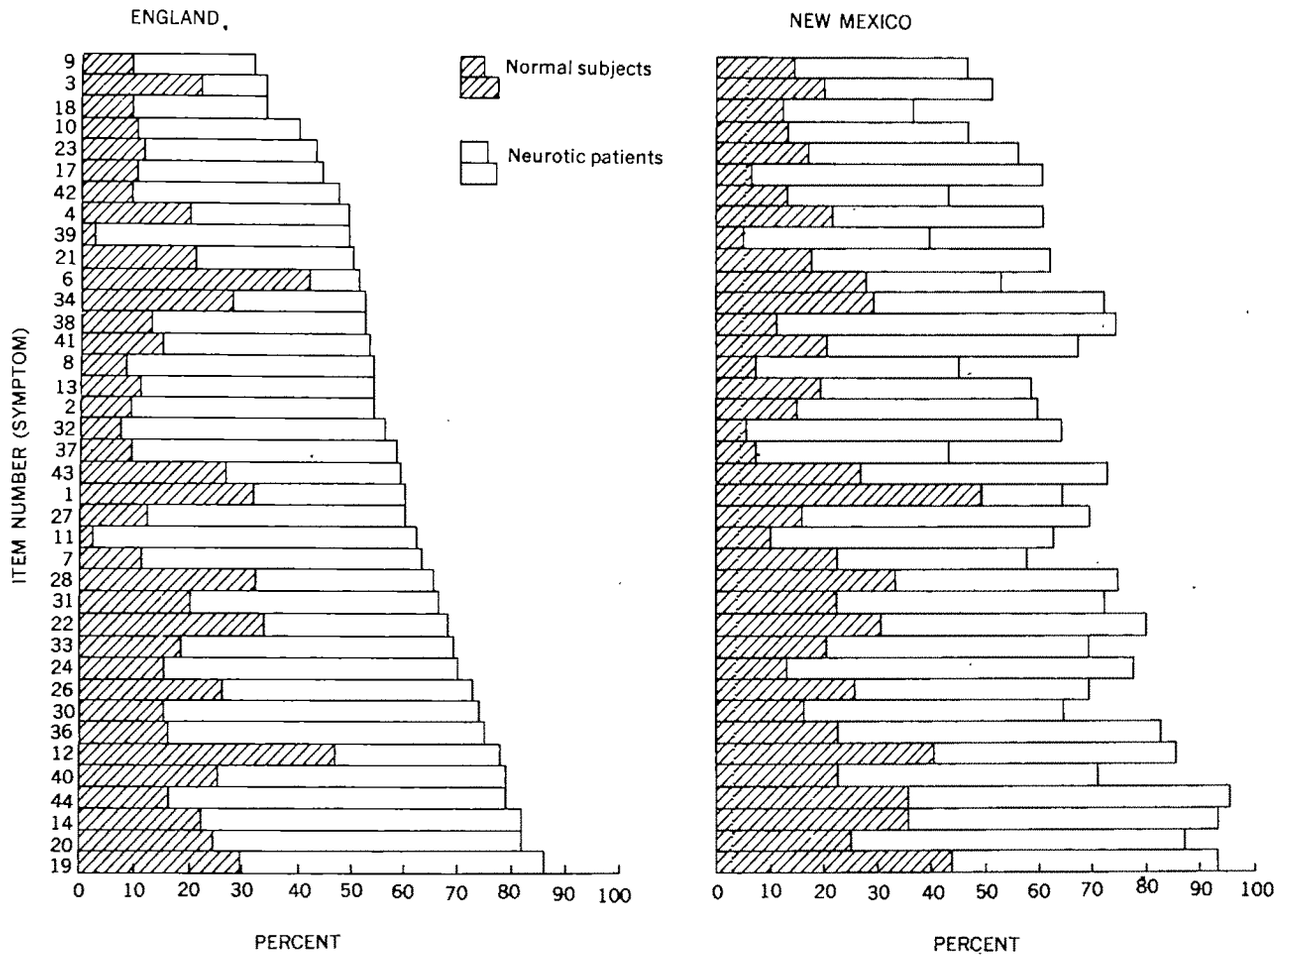
The One-Week Prevalence of Symptoms in Neurotic Patients and Normals

BY ROBERT KELLNER, M.D., PH.D., AND BRIAN F. SHEFFIELD

A questionnaire concerning the number of symptoms experienced during one week was administered to 100 neurotic patients and 100 normal subjects, first in England and then in New Mexico. The rank order of frequency of symptoms was similar on both sides of the Atlantic, but neurotics and normals had different rank orders. Both groups reported a high prevalence of symptoms, with neurotics reporting a significantly greater number of almost all symptoms.

SYMPTOMS REPORTED as having occurred during a short time can be important data in research in psychiatry, for example, in rating distress or in evaluating the side effects of drugs. The purpose of this study was to examine the self-reported occurrence and distribution of symptoms in normal subjects over a one-week period and to compare these findings with the self-reported occurrence of the same symptoms in neurotic patients. The study was carried out in England and repeated in New Mexico.

Dr. Kellner is Associate Professor, Department of Psychiatry, University of New Mexico School of Medicine, Albuquerque, N. Mex. 87106, and Mr. Sheffield is Senior Psychologist, Wesham Park Hospital, Kirkham, Lancashire, England.



This work was supported in part by grants from the Mental Health Research Fund, England, and the Liverpool Regional Hospital Board.

POPULATION AND METHOD

In the first study the normal group consisted of employees of a pharmaceutical firm and of a public health department. A letter was sent to unselected employees, asking them to participate anonymously in a study. In the letter the purpose of the study was briefly explained as a preliminary study of the effects of treatment. Of the 100 normal subjects selected, 58 were men and 42 were women. Their ages ranged from 17 to 60 years, with a mean of 37 years. There were also 100 patients chosen to participate in the study. Only those who had been diagnosed by the examining psychiatrist as neurotic were included. Of these, 52 were consecutive new outpatients and the remainder were consecutive inpatients and day patients at two hospitals in Liverpool, England. Their ages ranged from 18 to 60 years, with a mean of 33.8 years. There were 59 women and 41 men. The procedure used and the tests administered were the same for patients and normals.

The second study was carried out in Albuquerque, N. Mex. The same method and procedures used in the first study were adopted for this one. The normal group consisted of employees of a university department and members of a social club. There were 100 subjects—76 men and 34 women. Their ages ranged from 16 to 65 years, with a mean of 30 years. The patient group consisted of 100 consecutive outpatients, of whom 60 were

FIGURE 1
*One-Week Prevalence of Symptoms**

*See appendix 1 for a list of the symptoms. The symptoms are ranked according to the frequency of occurrence in the first group of neurotic patients.

women and 40 were men. Their ages ranged from 17 to 58 years, with a mean of 29 years.

In both studies the patient groups contained a larger proportion of semiskilled and unskilled workers than the normal groups, while the normal groups contained a larger proportion of persons from professional and managerial occupations.

All subjects were administered the pencil-and-paper form of the Symptom Rating Test (1). This test contains self-rating scales and a checklist of 15 somatic and 24 emotional symptoms (see appendix 1). They were also given a brief questionnaire concerning current illnesses and treatments. Each page of the checklist began with the question: "How have you felt *during the past week*?" This was followed by questions such as, "Have you had headaches or head pains?" "Have you felt dizzy or faint?" The responses available were "yes" and "no." Only the results obtained from the checklist will be reported here. The chi-square test was used to test for differences between patients and normal subjects. Differences at or below the conventional level of five percent were regarded as significant.

RESULTS

In figure 1 the symptoms are ranked according to their frequency of occurrence in neurotics in the first study. In both studies all symptoms occurred more frequently in neurotic patients than in normals. In the first study this difference was significant for 36 symptoms ($p < .001$). For two symptoms ("stomach pains" and "muscle pains, aches, and rheumatism") the difference failed to reach a significant level. In the second study all symptoms occurred significantly more frequently in patients than in normals (one symptom at the $p < .05$ level and the rest at the $p < .001$ level).

The American groups tended to show a higher one-week prevalence of symptoms than the corresponding English groups; no tests of statistical significance were carried out because the groups may not have been representative, and any differences in results may have been caused in part by the method of selecting the subjects.

The most common symptoms in neurotic patients were overt emotional ones. In the first study these symptoms were "worry," 86 percent; "tense," 82 percent; and "unhappy, depressed," 82 percent. In the second study the most common symptoms were "nervous," 95 percent; "worry," 93 percent; and "tense," 93 percent. In normal subjects the most common symptoms were somatic ones, the three most common in the first study being "tired," 47 percent; "muscle pains, aches," 42 percent; and "irritable," 34 percent and in the second study, "headaches," 49 percent; "worry," 43 percent; and "tired," 41 percent. Eighty-nine percent of the normals in the first study and 93 percent in the second study reported at least one symptom during the week of the study. Thus the experience of symptoms is apparently compatible with health.

Analysis of the data by age, sex, and social class showed that differences between the patients and the corresponding normal subjects had not materially affected the results.

In the first study one normal subject suffered from chronic bronchitis, one had substitution therapy for myxedema, and one had a minor respiratory infection during the week of the study. Five subjects were taking tranquilizers and eight were taking hypnotics at night. In the patient group, five had physical illnesses: One had osteoarthritis of the hip, one had neurodermatitis, one had chronic nephritis, and two had chronic bronchitis.

In the second study one normal subject had rheumatoid arthritis and one had peptic ulcers. Six of these normal subjects were taking tranquilizers, and nine others were taking hypnotics at night. Among the patients one each had spondylolisthesis, Hodgkin's disease, bronchial asthma, and cirrhosis of the liver. Most of the subjects in the patient groups were taking psychotropic medications.

In both normal groups, subjects who reported physical illnesses reported a higher mean number of somatic symptoms than the rest of the group. This was not found in the patient groups.

DISCUSSION

The high prevalence of symptoms and the rank order were similar on both sides of the Atlantic for normals and for patients. There were expected differences between patients and normals. The normal groups had a high prevalence of symptoms over one week, and a fairly large proportion reported symptoms suggestive of psychiatric ill health (for example, 15 percent and 12 percent reported "feeling unworthy or a failure," 13 percent and 9 percent reported that they were worried that they might have a serious illness, and 7 percent and 6 percent reported feeling that there was "no hope"). This is in accord with the findings in some epidemiological surveys in which a large proportion of subjects were found to be distressed and reported symptoms (2–5).

The proportion of normal subjects who reported overt emotional symptoms during one week was larger than the proportion of people who see a general practitioner for these symptoms during one year (6). It appears that only a small proportion of subjects who experience emotional symptoms will seek the help of a physician.

The differences in ranking between patients and normals were unexpected in that in both studies the most common symptoms in normals tended to be somatic, whereas in patients they tended to be overtly emotional.

A fairly large proportion of patients and normals in both studies reported symptoms that could easily be mistaken for medication side effects (for example, symptoms of feeling dizzy or faint, feeling nauseated or sick, heart beating strongly or quickly, and poor appetite). Most of the neurotic patients in both studies were taking medication at the time this work was done, but a large proportion of normals who reported these somatic symptoms were not taking any medication, nor did they report physical illness during the week of the study.

These findings suggest that the frequently reported placebo side effects (i.e., symptoms that patients report when given placebo) may largely be commonly occurring symptoms and not symptoms due to the suggestive effect of the placebo. The findings further suggest that unless a crossover placebo period is used as a baseline, an observer could get a false impression of the side effects of a new medication.

The two American groups showed a tendency to report more symptoms than the English groups. No conclusions can be drawn from these findings since these differences may have been due to biases in selection. Against this trend a few symptoms were reported more frequently in both English groups, i.e., heart symptoms (item 8), lacking self-confidence (item 40), and "feeling inferior to others" (item 37). These results might represent cultural differences but require replication.

Goal-Attainment Scaling as a Method for Evaluating Mental Health Programs

BY DAVID W. CLINE, M.D., DAVID L. ROUZER, PH.D., AND DAVID BRANSFORD

Goal-attainment scaling, a method for evaluating individual or group treatment programs, involves setting up individualized treatment goals and scoring the attainment of goals from the most successful outcome (+2) to the least successful (-2). Having the therapist and patient construct the scale helps to differentiate problems, structure therapy, and clarify outcomes. Over-optimism about the benefits of therapy may cause problems with score validity; measures for external validation are suggested.

A NEW METHOD for evaluating comprehensive mental health programs was reported in 1968 by Kiresuk and Sherman (1). The patients were randomly assigned to treatment modes and an individualized goal (or set of goals) was specified for each patient, the degrees of attainment or nonattainment of this goal being assigned a value on a numerical scale ranging from +2 to 0 to -2 and expressed as a standardized T score (with a mean of 50 and a standard deviation of 10). This method permits objective comparison of treatment modes within a total program.

More specifically, the procedure works as follows: After an initial diagnostic evaluation of a patient by an evaluating team, the goal selector (or goal selection committee) decides upon a realistic set of mental health goals for the patient and specifies for each goal a scale composed of a graded series of likely treatment outcomes, ranging from most to least favorable. At least two but preferably three points on each scale must have sufficiently precise and objective descriptions to enable an unfamiliar observer to determine whether the patient lies above or below that point. These points are then assigned numerical values: +2 for the most favorable outcome, -2 for the least favorable outcome, and zero for the outcome considered most likely.

The goal-attainment scale thus represents a transformation from a subjective judgment of treatment outcome to a random variable, with a mean of zero and a variance of one. The goal selector may also specify a set of weights for the goals, reflecting his appraisal of the relative value of each goal as an indicator of successful treatment. (For example, see table 1, where alleviation of depression was weighted 80 and improved peer relationships, 60.) The defined points may be directly or indirectly related to the mental health goal. For example (see table 1), a patient may have a mental health goal of "less dependency on mother," with the most unfavorable outcome thought likely (-2) being "Does not make even minor decisions without mother's advice," the expected level of success (0) being "Makes many of own decisions without feeling rejected by mother," and the best anticipated treatment

Presented in part at a panel discussion at the 124th annual meeting of the American Psychiatric Association, Washington, D.C., May 3–7, 1971.

Cline and Rouzer are Assistant Professors and Mr. Bransford is a medical student. Direct reprint requests to Dr. Cline, 412 Union St., S.E., Mayo Box 393, Minneapolis, Minn. 55455.

This work was supported in part by the Minnesota Medical Foundation and by Public Health Service grant MH-05921 from the National Institute of Mental Health.

success (+2) being "Consults with mother only on major decisions that affect her."

After treatment (including drug treatment, individual therapy, group therapy, and day hospital care) for a fixed interval (six months to one year), a follow-up worker contacts the patient and reviews with him his progress toward achieving the goal specified before treatment, thus arriving at goal-attainment scores that may be viewed as success-failure scores. The final step is computation of a composite goal-attainment score, which transforms the several goal-attainment scores into a single standard score with a mean of 50 and a standard deviation of 10. From this composite score one can determine whether further services are required or whether treatment has been successful.

This goal-attainment method may also be used to appraise an entire mental health program. Kiresuk and Sherman have begun such a research project under the auspices of the National Institute of Mental Health. Our own two-year experience with goal-attainment scaling as an educational tool, as a therapeutic tool, and as an indicator of success or failure with patients is reported here.

APPLICATIONS

Education of Therapist

The Psychological Treatment Unit of the Department of Psychiatry, University of Minnesota Medical School, began to use goal-attainment scaling early in 1969 (2). Each patient admitted to the unit, together with his therapist, constructed a goal-attainment scale. The use of therapist and patient to construct the scale is a departure from the procedure outlined by Kiresuk, who suggested that an independent goal selector design the goals without either the patient's or the therapist's knowledge.

Our method, although contaminating a clean research design, produced educational and therapeutic benefits. In our setting, where medical students, residents, psychology interns, and other mental health personnel are trained, there is often the problem of defining psychiatric patients' problems in such a way that they are meaningful for the student. Medical students in particular find it difficult to comprehend and to differentiate psychiatric problem areas. Goal-attainment scaling provides for these students a structure within which they can understand, appraise, and work in a therapeutic relationship with the patient.

For example, the patient whose attainment scaling appears in table 1 was obviously neurotically depressed and had dependency problems. Other than the diagnostic significance of this observation, the therapist was unable to comprehend various problem areas that manifested themselves within this diagnostic capsule. Goal-attainment scaling, which differentiated the problem areas (i.e., mother relationship, peer relationship, sex and dating, decision making, and the construction of a continuum of possibilities for change), clearly structured the psychiatric problem. Goal scaling was thus an educational tool by which the therapist could understand and then meaningfully work with the patient. It gave the therapist an organized sense of the specific problem areas and further pointed out the possibilities for therapeutic action.

The information on treatment outcome provided from follow-up, which in our setting ranged from four months to one year and was completed by an independent rater, has additional educational benefits: The beginning student therapist, as well as the permanent staff members, get a relatively clear picture of treatment outcome. The patient whose goals are described in table 1 showed a T score of 55 on follow-up. Since a score of 50 represents the expected level of treatment success, a score of 55 means that this patient had a slightly better overall outcome than expected. However, the rating in the area of dating and sex was at the less-than-expected level of treatment success; this area is clearly one where further help needs to be rendered. This type of feedback provides some closure to the treatment endeavor and, more importantly, a sense of process and temporal relationship. The patient described here came for treatment with a history of experiences that resulted in the difficulties depicted on his goal-attainment scale. During his experience with the treatment unit, he made some changes that, at one-year follow-up, showed improvement in many of the areas of previous difficulty, even though more work remained to be done in others. This patient's status is an evolving process; we intervene and follow his course—structuring, organizing, and quantifying by the goal-scaling technique.

Therapeutic Aspects

When the patient participates in defining problem areas and in documenting the continuum of possibilities for change, he also derives therapeutic benefit. Goal-attainment scaling helps him sort out problem areas in specific terms and, furthermore, is a basis on which a therapeutic contract can be made. The patient previously mentioned came for treatment realizing only that he was depressed. Further exploration into that problem revealed to him his stifling dependency relationships. The goal-attainment scale he worked out with the therapist provided a structured framework within which he could commit himself to a treatment contract. With specific goals in mind he set out, with the therapist's help, to modify his behavior. When the primary tasks of treatment are clearly established, therapy is less likely to become directionless and meaningless: Good therapy has the quality of goal directedness, and goal-attainment scaling helps make this manifest.

Assessing Treatment Programs

As Kiresuk and Sherman have stated (1), goal-attainment scaling may be used in any context where quantifying progress would enhance efficiency and productivity. Thus, it is possible to use the Kiresuk procedure to assess the adequacy of a treatment program in much the same way individual treatment is assessed. This can be done very simply by randomly selecting N individuals

TABLE 1

Kiresuk Goal-Attainment Scale

Outcome Value	Goals (Goal Weights)				
	Alleviation of Depression (80)	Less Dependency on Mother (80)	Improved Peer Relationships (60)	Increased Dating and/or Successful Sexual Relations (70)	Vocational Success (50)
−2: Most unfavorable treatment outcome	Suicidal thoughts and gestures, feels chronically depressed.	Does not make even minor decisions without mother's advice.	Does anything for anyone to buy friendship.	No dating or one date a month.	No employment.
−1: Less than expected level of success with treatment			Says no to friends' selfish demands.		Odd jobs periodically.
0: Expected level of success with treatment	Occasionally feels depressed and has passing suicidal thoughts but no gestures.	Makes many of own decisions without feeling rejected by mother.		Calls girls for dates and has a date, with petting, once a week.	Steady work as blue-collar worker.
+1: Greater than expected level of success with treatment			Concerned with needs of others and has respect from peer group.		
+2: Best anticipated treatment success	No feelings of depression; no suicidal thoughts.	Consults with mother only on decisions that affect her.		Marriage with satisfactory sexual relationship.	Skilled laborer.

from a patient population and finding the mean goal-attainment score. If this score were significantly below expectancy, the thoughtful investigator would entertain the notion that this therapy program needs revamping.

Of course it may be argued that patient improvement is only one of several aspects salient to program evaluation. To aid in evaluating a program, one might wish to specify other goal dimensions, each having its own concrete reference so that an objective observer could rate degree of attainment, cost of care per patient, staff morale, the consistency with which staff members treat patients, length of hospital stay, relapse rates, and whatever other possibilities one could think of for rating a program. We have not yet begun to evaluate our program at this more complex level.

RETROSPECTIVE STUDY

In order to gain experience with goal-attainment scaling and to evaluate how well we were doing with patients in our care, we designed a retrospective study using this scaling technique. Two research associates reviewed evaluation intake data (psychiatric, social work, nursing staff, and psychological testing) for 39 patients and then constructed goal-attainment scales for each of these patients. Without knowing the patients or treatment modalities used, these same researchers contacted each of the subjects for follow-up evaluation and then calculated the goal-attainment scale. The mean T score for this group was 39, with a standard deviation of 10, which indicated that these patients were at the less-than-expected level of success with treatment (−1). This result implies either that treatment had been relatively ineffective, or that the goal-attainment scalers had been overly optimistic in assigning the expected level of treatment success. Review of the goal-attainment scales from this sample showed that over-optimism about results was the more influential cause here, and, in turn, suggested the need for greater emphasis on training, diagnosis, course of illness, and expectancy for treatment.

As our retrospective study indicates, the Kiresuk goal-attainment scaling procedure does not automatically guarantee appropriate designation of expectancy levels. Another aspect of the procedure that leaves room for error is the selection of goals, which is heavily dependent upon the therapist's skill and experience in assessing the sociopsychological factors underlying disturbed behavior. Thus, it is possible that the changes indicated by an individual's goal-attainment score are trivial or irrelevant to his total adjustment. If this is the case, there will be a preponderance of high scores but no significant change in rates of remission.

It is therefore desirable to check the goal-attainment scale against some external criterion of adjustment. The Minnesota Multiphasic Personality Inventory (MMPI) is a well-known, objective personality questionnaire with known validity as an index of adjustment. Our initial ex-

plorations of the relationship between changes on the MMPI from admission to discharge and on the goal-attainment scale suggest the possibility that sex and personality type influence the correlations, but our sample is too small to report detailed findings at this point; we mention them only to suggest the need for further research along these lines.

CONCLUSIONS

Goal-attainment scaling is valuable in the psychiatric education of the therapist, as a therapeutic tool, and as a means of assessing treatment outcomes. The successful use of this scale implies substantial knowledge of the patient's problems and realistic expectancy levels for outcome. We feel that the reliability of this procedure can be enhanced if follow-up is repeated over an extended period of time, since mental health, like health in general, is usually a fluctuating state. This procedure has potential merit in evaluating other programs, such as the training of students, interns, or residents.

LETTERS TO THE EDITOR

The Role of Psychiatry in War and Poverty

SIR: In the section on social issues of the "Report of the Trustees' Policy Meeting," March 1971 (September 1971 issue), the statement is made that all five groups comprising the Plenary Assembly "were unanimous in endorsing the resolution passed by the Assembly of District Branches. . . ." That resolution included a statement that "local, national, and international political, social, and economic policies may produce psychological forces which can affect mental health and illness and which can reduce personal dignity, destroy life, and increase human pain and disability. . . ." In spite of this unanimous endorsement the report subsequently states, as the sense of the plenary discussion, that "none of the issues mentioned" (i.e., poverty, children, youth, social planning, violence, etc.) "were viewed as irrelevant *other than the war issue,* and not even that would be irrelevant *if some scientific evidence could be mustered to demonstrate its relationship to psychiatry*" (italics ours). A statement is also made (not necessarily as a position of the Plenary Assembly) that war and poverty are issues "in which psychiatry *may* have a role" (italics ours).

To state or imply that the relationship of war or poverty to mental health and illness is still scientifically in doubt or that psychiatry *may* have a role in relation to these is indefensible at this point in psychiatric awareness. Such conclusions can only represent a reluctance to take stands on politically, but not psychiatrically, controversial issues and as such constitute a failure of social responsibility on the part of participants in the plenary session.

This conviction, as it relates to war, has received support from the APA Board of Trustees itself in a resolution of May 6, 1971 (July 1971 issue). It reads:

> BE IT RESOLVED:
>
> That the Board of Trustees of the APA wishes to add its voice to that of the great masses of the American people who have so firmly expressed their agony concerning the war in Southeast Asia. Also, as psychiatrists we have specialized deep concerns about its grave effects on morale and on the rise of alienation, dehumanization, and divisiveness among the American people.
>
> THEREFORE:
>
> The Board hereby expresses its conviction that the prompt halt to the hostilities in Southeast Asia and the prompt withdrawal of American forces will render it possible to reorder our national priorities to build a mentally healthier nation.

We the undersigned affirm our conviction that issues of war and poverty in our time are two of the most profoundly important social issues with which psychiatry is confronted. Organized psychiatry has both strong moral responsibilities and scientific bases for position statements about these issues.

"Diagnosing" Political Candidates

SIR: Although I am substantially in favor of the strong advocacy of alternatives to war in settling disputes between nations, I am filled with disgust by the sanctimonious smugness of a number of members of our profession who use business and scientific sessions to pontificate on the evils of warfare in Southeast Asia.

I consider these pronouncements to be in bad taste for several reasons.

First, the statements are so provocative that in my opinion they should be answered, since they are often sweeping generalizations with only hints of scientific validity. I did not take the floor at the forum following the 1972 annual business meeting because I considered it improper to harangue the majority on what I feel is essentially an issue that should be handled politically by individual members of the organization.

Second, the statements are unequivocally biased. No mention is ever made in these statements of the aggressive role of the Viet Cong or the North Vietnamese. They are always addressed more or less specifically to Mr. Richard M. Nixon, and his name is bandied about and cussed and discussed rather freely. The purpose of these statements, which unilaterally condemn the actions of our government, should be obvious, and I cannot comprehend an organization of responsible scientists accepting such faulty logic.

Third, though the gentlemen and ladies making these statements do so in profound, solemn tones, these same voices become angry, strident, cutting, vicious, nasty, and even virtually obscene whenever their rationale is questioned.

If this is not evidence of defense of an irrational position, then what in heaven is? Those preaching nonviolence are among the rudest, coarsest people I have seen in some time if they do not get their way.

One such gentleman under the guise of "clinical discussion" gave a capsular diagnosis of Mr. Nixon's personality. Doing this is preposterous and absurd besides being in very poor taste. This man was not Mr. Nixon's psychiatrist. As far as I know he had never examined him. This is tantamount to my saying, "Mr. McGovern has a reaction formation against even normal aggressiveness because otherwise he would release anal-sadistic feelings and impulses and commit not war, but matricide." Of course I do not have any idea what is right or wrong with Mr. McGovern in a psychiatric sense. These comments were almost in the nature of the situation at *Fact Magazine* a few years ago when psychiatrists were asked to "diagnose" Barry Goldwater. These same individuals who so glibly "diagnose" political figures they do not agree with strongly condemn the idea of giving psychiatric examinations to rabble-rousers, radicals, rioters,

and general malcontents who call this "political imprisonment." What a contradiction in ideology and ethics!

I am sorry to have had to write this letter. Perhaps I should have expressed my views in the open forum, but then, correspondence may be a more effective way of opening the whole area for discussion among the membership. A vote return of 63 percent by the general membership is not very healthy, particularly when two elections were so close in tally.

I am a concerned psychiatrist, not Concerned. I fear the inroads of social-liberalism and the consequences it may have for a psychiatry based not on logic, scientific reason, and common sense but rather on sociopolitical ideology.

I wonder how everyone else feels.

Mental Health of Political Candidates: Notes on Abraham Lincoln

SIR: In light of recent discussions concerning the health of candidates for political office, the following notes about Abraham Lincoln and his family are relevant.

Lincoln's mother was born out of wedlock. His maternal grandmother, Lucy Hanks, was investigated by a grand jury for immoral tendencies—as "too free and easy, . . . too wild in her ways." She later married and quieted down (1). In his late teens or early 20s, Lincoln himself went through a wild period, engaged in fights, and wrote a long-winded and insulting poem. He was pointedly not invited to a family wedding because of his unpredictable behavior.

When Lincoln was 29, following Ann Rutledge's death it was "rumored his reason was in danger." He had "fits of mental depression, . . . wandered up and down the river and into the woods, woefully distracted, . . . filled with indescribable grief." His friends watched him and, fearing suicide, finally sent him to another town where he remained for some weeks and was gradually brought back to his reason. From then on, however, his spells of melancholy became more intense. He wrote to a Dr. Drake in Cincinnati, describing his mental condition, but Drake would not "prescribe . . . without a personal interview." From about ages 29–32, Lincoln did not dare carry a pocket knife when alone (2).

When Lincoln was 31 (January 1841), he did not show up for his scheduled wedding to Mary Todd. Joshua Speed and his other friends "watched him closely day and night," and kept knives and razors out of his reach. On January 19, 1841, the Illinois legislature was informed of Lincoln's inability to attend its sessions. On January 23, Lincoln wrote: "I am now the most miserable man living. . . . I awfully forbode I shall not be better." He wrote lines on "suicide" to the *Sangamon Journal*, which were later cut out of the paper. He was sent to visit Speed's mother in Kentucky, and by autumn 1841, he had apparently recovered, writing to Speed: "I have been quite clear of hypo since you left." He resumed his legislative duties and married Mary Todd. Herndon and Weik reported in his biography that Lincoln's melancholy was "necessarily hereditary, . . . ingrained, . . . could not be reduced to rule or the cause arrayed." It was "part of his nature and could no more be shaken off than he could part with his brain."

Certainly Lincoln had severe affective disorder, perhaps of the bipolar type. He would probably have received antidepressants or electroconvulsive treatments if such therapy had been available then. Since he is generally acknowledged to have been our greatest President, it would seem that his prior disorder did not disqualify him for the office. Had he suffered from it in severe form during his term of office, he would, of course, have temporarily been unable to function. In 1972, however, he could have been treated promptly.

A Brief Comment on Human Sexuality

SIR: As an editor myself (*Archives of Sexual Behavior: An Interdisciplinary Research Journal*), I am reluctant to write a letter to the editor. It is time-consuming to read them, let alone to write them. However, a paper we currently have in press contradicts Daniel Offer's editorial comment ("Human Sexuality," April 1972 issue): "Findings from recent studies . . . have revealed little change in sexual behavior during the past two decades."

Schmidt and Sigusch (1), in Hamburg, have found:

> The age at first masturbation . . . for girls of high educational level . . . dropped markedly during the last decade. . . . The age at first coitus decreased markedly. . . . Reduced to a simple formula, we can say that the 16 and 17 year olds of today behave like the 19 and 20 year old of 10 years ago.

Psychiatry and Neurology

SIR: In criticism of Dr. David E. Raskin's choice of the "marriage" metaphor describing the relationship between psychiatry and neurology (Letters to the Editor, May 1972 issue), I would substitute another: Neurology is psychiatry's "anchor" to scientific medicine.

Psychiatry is particularly handicapped by the fact that any transitive act by a physician will relieve basic psychiatric emotion and anxiety and produce a satisfied, if not improved, patient. Drugs, nude therapy, social science, abortion, anoxia, and psychology—all reduce anxiety (has it been noted at NIMH or elsewhere that no agent generates that affect?), the result being pressure upon the psychiatrist to add to his therapy that which appears warmest and brightest from his philosophical horizons. With a covey of satisfied patients, it is human for the physician to overlook that such therapies breed addictions to drugs, to social action, or to the physician. The medical progress of these therapies is, at best, sidewise.

Neurology, the medical science of determinative anatomy and physiology, is our precious link to scientific medicine, which bids us to attend the healthy person with medical complaints but to commit no therapeutic intervention in the absence of objective and demonstrable disease.

Dumping of Patients: Funding and Statistics a Problem

SIR: The footnote giving the position titles of the authors of "The Hospital 'Dumping Syndrome': Causes and Treatment" (May 1972 issue) is an important factor in the success of their policy change that reduced dumping of patients. Drs. Wilder, Karasu, and Kligler are all members of the faculty of Albert Einstein College of Medicine, Bronx, N.Y. Dr. Wilder also serves in the Department of Psychiatry of the Bronx Municipal Hospital Center. The Director of Bronx State Hospital, Dr. Israel Zwerling, is also head of the Department of Psychiatry at Albert Einstein College of Medicine. All three institutions—Bronx Municipal Hospital Center, Bronx State Hospital, and Albert Einstein College of Medicine—are part of the same teaching complex. It seems to me that these administrative factors played an important part in effectuating an accommodation between the two hospitals in reducing the practice of dumping patients. Certainly Dr. Wilder and associates are to be complimented for recognizing the problem and for doing something about it in their community.

However, financial considerations cannot be overlooked as a cause for the "dumping syndrome." When state mental hygiene budgets are drastically cut and the length of stay in state hospitals is limited to 90 days, dumping of patients from the state hospital into the community and its agencies is a direct result. This dumping situation becomes further aggravated when funds are not available for adequate aftercare services for those patients who have been prematurely discharged into the community.

While Dr. Wilder and associates have been able to reduce dumping between a municipal hospital and a state hospital, the same results might not be so readily achieved were the municipal hospital a voluntary institution and without the joint academic affiliations. Dumping of patients from one institution to another arises when funding for services is inadequate and when patient turnover and numbers served become overriding considerations in the administration of mental health services.

I am the executive director of Altro Health and Rehabilitation Services, Inc., which operates Altro Work Shops, Inc., a rehabilitation and vocational training center located about two miles from both the Bronx Municipal Hospital Center and Bronx State Hospital. Altro Work Shops, Inc., as a voluntary agency in the community, maintains close cooperative relationships with the rehabilitation programs at the Sound View-Throgs Neck Mental Health Center and at Bronx State Hospital. Both institutions refer patients to Altro Work Shops for vocational rehabilitation. As a result of the close tie lines and cooperative relationships that have developed over the years with these mental health institutions, there have been few instances of dumping patients into Altro's community rehabilitation facility. However, where such relationships have not been developed, dumping will result for the right reasons—i.e., because the professional staffs at the state hospitals are concerned about their patients and see the existing community resources as a place where the patient will receive at least "holding" aftercare services.

Cooperative relationships between state, municipal, and voluntary mental health services will, of course, always assist in alleviating and in reducing the damage done to patients by shortsighted legislators, budget makers, and bureaucrats; but even the best and firmest of such arrangements will require adequate funding in order that the focus be placed upon patient care and service rather than upon cost benefits and statistics of patient turnover.

BOOK REVIEWS

Helping People: Karen Horney's Psychoanalytic Approach, *by Harold Kelman, M.D. New York, Science House, 1971, 614 pp., $18.50.*

This is not a biography of the life and thought of Karen Horney in the usual sense. Dr. Kelman takes a much more creative approach. He reveals what he considers to be the essence of Horney's theories and her style of treatment by presenting much clinical and theoretical material based on his own 30 years of experience as a psychoanalyst. Considerable space is devoted to the process of training student analysts. All this is done in the spirit of Horney.

Interwoven with the case material is much discussion of Horney's theory of personality as well as other theories that influenced her.

Dr. Kelman describes himself as a holistically oriented analyst, with emphasis on therapy as an *experience* involving patient and therapist. He quotes Freida Fromm-Reichmann as having said, "A patient wants an experience, not an explanation." Both Fromm-Reichmann and Horney felt that process and current experience are more important than content and rigid technique. Rigid theories are only the loosest kinds of guides. The therapist must be free to be innovative. Theory must be expressive of the time, place, and person of the patient. The images Horney used included, where appropriate, the values from a variety of different orientations, from the mind of the East, from the mind of the West—Freudian, post- and neo-, phenomenological, existential, and Oriental.

Along with great flexibility, Kelman stresses the need for regularity, continuity, and consistency in the timetable, although the schedule of frequency and duration differs markedly for different patients and at different times in the process of therapy. Kelman underlines the importance of dreams by devoting nearly 100 pages to the subject.

Far more than most books, Kelman's conveys a great deal of the "feel" of what goes on in analysis. Along with this, he discusses many details of technique, from note taking to subtle maneuvers of interpretation. Reading the book is a moving experience.

Masserman recommends it as imperative reading for those who wish to broaden and humanize their orientation and to improve their clinical skill.

This volume does not present a summary of Horney's theories and treatment. It could have been more helpful if it had presented, in outline form, the essence of Horney's contribution and theory. (This could be included in a second edition.) It is not a critical study of Horney.

Horney's contribution started with emphasis on social factors, as opposed to Freud's biological and instinctive emphasis. She began with basic anxiety, not the castration complex as with Freud and Melanie Klein. Basic anxiety is the result of disturbed security of the child in relation to his parents and, later, to society. Basic anxiety is related to basic hostility. The methods developed to cope with feelings of insecurity and isolation can find expression in three broad pathways or areas. Moving toward people is the need to love; moving away is the need for independence; and moving against people is the need for power. Neurosis develops when one of these aspects develops one-sidedly. When there is love, warmth, security, and respect such difficulties are avoidable. Conflict is thus not instinctive and inevitable but the result of social conditioning.

In contrast to the biological and mechanical emphasis of Freud, Horney started with the need for security as opposed to the instincts of sex and aggression. The various strategies coping with helplessness and isolation are drives or needs. There are neurotic and irrational needs. From the interplay of needs, conflicts develop. Vicious circles are set up. For example, the need to be independent aggravates the need to be loved. The idealized image is created in which contradictory trends disappear—but actually are only repressed. Therapy is a disillusioning process in helping the real self (as opposed to the idealized or fictionalized self) become more developed. A central inner force is the source of a free healthy development of personality potential. There is a struggle between the constructive forces of the real self and the obstructive forces of the pride system, between healthy growth and the neurotic drive, to prove the fictionalized perfection of the idealized self. Thus Freud is biological and pessimistic, whereas Horney is cultural and optimistic.

Femininity was determined by Freud and Helen Deutsch only secondarily—a girl child's early sexual development is parallel to that of the boy. Phallus envy is the central influence in the development of the female castration complex. Horney held, on the contrary, that the earliest phase of the girl child's attachment to the father is patterned after the mother. According to Horney, the wish for a child is thus a primary feminine attitude, whereas according to Freud, the wish for the phallus is primary and only secondarily is there a turn to femininity.

An interesting account of medicine's rather traditional, dehumanized attitude toward terminal patients is contained in a quotation from Kübler-Ross's book, *On Death and Dying* (1, p. 444). Dying is preceded by a kairos experience in which the patient is understood and the possibility of dying with dignity is returned to him. There is a "caring concern of a good friend, a wise spiritual counselor, or a Hippocratic physician who humanly and realistically supports [the patient's] hope [that a cure will be found]."

Kelman's *Helping People* is a monumental scholarly, optimistic, helpful, humanistic study. Indefatigable, unyielding travail and a search for health and wholeness has been the journey of psychoanalysis following Horney. She was a leader, pioneer, and explorer in the conquest of illness and suffering. Young psychiatrists considering psychoanalytic training will be intrigued by this book.

Kelman's book includes a complete bibliography of Horney's work. We feel that readers wishing to further study her theories will be helped by reading the works of a number of other authors who have emphasized various aspects of her work (2–9).

"Psychopathology" in its many indelicate details has been brought out strikingly in literature. For example, *Portnoy's Complaint* (10) traced development from masturbation to guilt and impotence—to humiliation and looseness of personality organization and behavior. The cultural and familial origin of all of this is derived from Horney's emphasis on cultural contributions to neurosis, and is illustrated by the different and contrasting characteristics of the society, whether affluent and competitive or cooperative and collaborative,

as contributing to the strength and health of the individual.

Death and the College Student: A Collection of Brief Essays on Death and Suicide by Harvard Youth, *edited by Edwin S. Shneidman, Ph.D. New York, Behavioral Publications, 1972, 207 pp., $4.95 (paper).*

The introduction to this book, the foreword, and the preface are written by men who speak with authority on the subject matter at hand. Farnsworth is nationally known for his work with college students in their various moods over a period of 40 years, and Shneidman, Professor of Medical Psychology at UCLA and erstwhile Chief of the Center for Studies of Suicide Prevention, NIMH, is an authority with long experience in the field of suicide prevention.

Except for chapter 4, "Combat Death," written by a Viet Nam veteran, the contributors were all Harvard students. The book makes for fascinating, if somewhat lugubrious, reading. Dr. Shneidman began a course in the Harvard undergraduate school on the "Psychology of Death," and a room that had 20 chairs drew 200 students the day the course began. All of the papers in this volume come from that course.

The 19 essays consist of brilliant personal reflections and contemplations of death as seen in active, if somewhat disturbed, young minds. One is impressed by the variety of approaches taken by the writers and the lively reporting of their musings and feelings. The essays range from "Death Is Alive and Well in the Ghetto" through "Hope and Suicide in a Concentration Camp" as seen from the perspective of an author 25 years later. The contents include "Growing Old, Death by the Installment Plan," on up through chapters on death in the philosophy of Sartre and of Unamuno, plus a section concerned with films and books on death.

It is difficult to single out any one chapter for special mention, for all of them are interesting and well written. "Death Is Alive and Well in the Ghetto" is reminiscent of the things we read about in the daily newspapers. The surroundings are distressing and life is cheap. There seems to be a large number of men willing to die, for they see little hope in their condition and see less to live for. The chapter that recalls to us the Nazi concentration camps is unrelieved horror. It is a wonder anyone came out alive. Apparently, from the behavior of their persecutors, the inmates were not meant to do so.

One young man placed an experimental classified ad in the newspapers which indicated that he intended to destroy himself unless someone could convince him of a good reason why he should not. He gave people three weeks to respond and sat back to see what would happen. His ad brought forth more than 100 letters voicing varying degrees of concern and indicated to him that there *were* people who really cared for others in distress.

The chapter on "The Funeral Industry in Boston" is reminiscent of the works of Jessica Mitford (1) and Evelyn Waugh (2). Both of those books shook up the undertakers—pardon me—funeral directors for a time, but the conversion didn't take with some and was soon forgotten by others. This chapter does not entice one to think of funeral directors with affection.

The chapter on the "Death Cult of James Dean" is fascinating. The cult was born on the day this surly, rebellious young man died in a sports car accident. The public, the author notes, went necrophiliac as the cult gained momentum. There were more than 2,700 persons at his funeral in his tiny hometown. Eleven months later he ranked number one in Photoplay magazine's actor popularity poll and drew 1,000 fan letters per week.

The chapter on "The Wake" and its significance gives good insight into the emotions of the participants in that particular import from abroad. Wakes undoubtedly serve a good purpose when kept in control. The portions of the book dealing with "Monolithic Daddyism" and chapter 11, titled "Manny Rap" (sic), were both a bit difficult for me.

Farnsworth comments that contrary to what might be expected, the rise of student despair and alienation has not caused waves of suicide, nor has experimentation with drugs and loss of confidence in and disillusionment with societal modes of regulation. "Private hopelessness or despair," he says, "rather than distress concerning public developments that is shared with one's peer group, is the paramount motive for suicide."

All who deal with young people of college age will want to read this book. It is not hammock reading, and it is not for taking along on one's honeymoon, but rather, read at a well-chosen time, it will bring insight and enlightenment regarding some wonderful, if confused, young people.

Commenting upon their actions has always been a penchant of older folks, and this probably contributes to keeping the latters' blood pressure in the higher ranges. We need say no more.

F.J.B.

Genetic Factors in "Schizophrenia," *edited by Arnold R. Kaplan, Ph.D. Springfield, Ill., Charles C Thomas, 1972, 635 pp., $43.*

For the psychiatric clinician, this large volume may best be considered as a postgraduate course in the methods and problems currently associated with the genetic theory of schizophrenia. In one of the chapters dealing with critical appraisal of the various theories, it is pointed out that the clinician, qua clinician, is apt to be the eclectic, satisfied with theories that help him treat disease, vague or untestable though they may be. Most psychiatrists today, whether interested mainly in physiological methods or in psychotherapy, will include inborn factors in their list of causes of mental disorder. Many will be aware of the studies of families, twins, adoptees, and high-risk

offspring that over many decades have helped to organize thinking about schizophrenia; probably few will know enough about current research to deal critically with the conflicts among genetic theories, as well as their nosological implications and their relation to environmental variables.

For those who have prepared themselves by reading both classic and recent studies, Kaplan has assembled 34 distinguished contributors to weave a counterpoint of research data, hypothesis, and commentary. One major theme is the interdependence of diagnostic and etiological understanding. Schizophrenia research has a long and honorable tradition in medical genetics, but its unique difficulties have caused it to fall behind in the current race toward specifying molecular mechanisms. The aim of many of the chapters—to match specific psychopathology with specific predisposition—therefore is clear, but far from achieved.

Regarding nosology, the book contains many important discussions bearing on clinical heterogeneity, including process-reactive or typical-atypical dichotomies; while the very concept of schizophrenia is opened to question by some of the contributors (as the title of the book implies). At the same time the various arguments for single-gene, multifactorial, and genetic heterogeneity theories, as well as some biochemical and cytological hypotheses, are presented authoritatively and in detail by their proponents.

Among its other riches, the volume contains clinically oriented chapters on the relationship between childhood and adulthood schizophrenia, on genetic counseling, and on the study of high-risk children and their parents, as well as a fascinating follow-up story on the Genain quadruplets (1).

The book has the virtue of presenting specially written articles rather than a conference report, but even so there is some duplication of material. Although it contains a discussion section in which various authors comment on the earlier chapters, the editor himself actually does the best job of tying together the threads in his concluding statement.

To give the names of the contributing authors would require listing every one; suffice it to say that many of the well-known schizophrenia researchers on the national and international scene are included. The book contains a glossary and a very useful author reference index.

The economics of publishing have unfortunately caused a rather high price to be set on this book. Still, it is not an introductory work, but rather it thoroughly explores the implications of genetic studies in schizophrenia. For clinicians sufficiently informed and sophisticated to look beyond prematurely simplified explanations, and for current or prospective researchers, this book is strongly recommended supplementary reading.

JOHN D. RAINER, M.D.
New York, N.Y.

The Public Challenge and the Campus Response, *edited by Robert A. Altman and Carolyn M. Byerly. Berkeley, University of California Center for Research and Development in Higher Education; and Boulder, Colo., Western Interstate Commission for Higher Education, 1971, 124 pp., $3.50 (paper).*

Colleges and universities have probably never been under such heavy criticism (or even attack) from so many sources as at present. Professor Brand Blanshard said many years ago that American education cannot have been too bad, or else it would not have produced so many excellent critics of itself. Certainly there is no current lack of critics, but whether most of them are excellent or mindless is a point at issue.

In this volume there is sharp but friendly debate regarding many aspects of the present low esteem in which college faculties and students are held by many people. Representatives of college administrations portray the concern of the public over what is perceived to be a gross lack of responsibility on the part of college faculties in controlling student disturbances. They also point out that such concern is usually met with hostility by both student and faculty campus leaders toward the fact that the public should be critical. Academic freedom, the tenure system, research work, and consultation work with public institutions are all under attack in various ways.

President Silber of Boston University makes an excellent plea for colleges to be headed by scholars who have administrative ability, rather than by persons trained primarily in administration. He also decries "the pointless obscenity and public abusiveness of many faculty members."

Warren Martin calls for a conspiracy for the future involving a fundamental change in our state of mind (malaise and confusion) and a drastic reordering of national priorities. The conspiracy would be one of conscience and humanity, one calculated to develop self-control of man before the world of his own making goes out of control. Walter Metzger discusses the academic profession in terms of its role in expressing a deep-seated desire in human beings to ennoble and sanctify human work. "To feel called, not driven, to one's vocation is to define a happiness no modern prospect can approach."

President McGill of Columbia University discusses the necessity for faculty members to act with honesty and integrity at all times, noting that only the faculty members can enforce their own standards. Some of his examples of faculty militants' dishonesty are real eye-openers.

At present it is difficult for a dispassionate observer to know who is more confused about the role of the universities and the issues that are seriously weakening them—faculty members or students. Yet it should be obvious as to who should be the most effective and active in developing and maintaining those standards which make a free, decent, and responsible life possible. A perusal of this volume should help in developing constructive programs for continued growth and renewal of the sources of our greatest hope for a life worth living—our colleges and universities.

DANA L. FARNSWORTH, M.D.
Boston, Mass.

Explanation in the Behavioural Sciences, *edited by Robert Borger and Frank Cioffi. New York, Cambridge University Press, 1971, 515 pp., $15.*

This volume is a collection of 12 essays ranging in subject matter from a discussion of the Skinnerian analysis of behavior, focusing mainly on the nature of responses, to Toulmin's essay on reasons and causes, which attempts to place causality on a continuum from behavior as an empirical phenomenon to behavior as a mediated phenomenon affected by basic brain mechanisms. These essays are extremely interesting reading, but will hardly offer any real practical applications to mental health practitioners busy with the vicissitudes of human behavior. For this reason it is quite unlikely that this book of readings will be widely popular with psychiatrists or with psychologists who are more interested in practical application than in theory.

Nevertheless, a number of these papers, with accompanying

criticisms by experts in the field, are fascinating reading and should appeal to those professionals involved in some of the more complex issues in the practice of psychiatry. For example, Toulmin's essay "Reasons and Causes" discusses exactly those considerations which one must go over when thinking about such problems as responsibility and justification of certain kinds of behaviors in criminals, patients with vague types of seizures (particularly where aggressive behavior is concerned) and the problem of responsibility for behavior in the individual with a drug-impaired state of awareness.

Of equal interest is I.C. Jarvie's "Understanding and Explanation in Sociology and Social Anthropology," which focuses on the problem of understanding behavior in individuals from different cultural backgrounds. Although the paper is basically a restatement of facts that are becoming more clear to us in the relationship of American society to its large minorities, the case and the problems are well stated.

For the reader interested in trying to understand the logic used to arrive at what looks on the surface like an illogical decision, Watkins' paper "Imperfect Rationality" will prove to be a fascinating discussion of the subject, particularly his case study of the logic in Vice-Admiral Tryon's maneuver of H.M.S. Victoria at Tripoli, which resulted in his death and the sinking of two of his flagships.

Like a smorgasbord, this collection has a little something for everyone, including a well-written paper by Boakes and Halliday, "The Skinnerian Analysis of Behaviour," which focuses primarily on Skinner's book *The Behavior of Organisms* (1). This article should be of particular interest to psychiatrists who have been bombarded recently by the input from learning theorists. It gives a fairly accurate description of the reasons why learning theory has been able to answer a number of the criticisms that have been continually leveled at the traditional approaches to psychotherapy. For those who are not particularly enamored of Skinner, Pribram's comment on the Boakes-Halliday paper makes the concise but explicit criticism of the Skinner position that it fails to take into consideration the operations of the organism in modifying the stimulus-response system.

For those who espouse the behavioral position and find themselves highly critical of the psychodynamic position, Cioffi's essay "Freud and the Idea of a Pseudo-Science" is an atom bomb of criticism that levels the psychoanalytic edifice for miles around.

Overall, it was a pleasure to read this volume. But it was also a chore because of the circularity of some of the reasoning, the endless preoccupation with the nuances of the philosophy of science, and a reengagement of free will and determinism, which, when the reading is finished, leaves you just about where you were when you started. Nevertheless, that seems to be where we are in the explanation of behavior, and all of the contributors and their critics seem to have done an excellent job in presenting their points of view.

Apparitions and Ghosts: A Modern Study, *by Andrew MacKenzie. London, Arthur Barker, 1971, 176 pp., £1.75.*

Psychiatrists have such familiarity with hallucinations in mentally ill persons that they may easily think, and even be taught, that hallucinations occur only in relation to other evidences of psychopathology. This is not true. Since the last decades of the nineteenth century (1), abundant evidence of hallucinatory experiences among sane persons has accumulated. From time to time articles on the subject appear (2), and these help to remind us that (according to some surveys) more than ten percent of all persons questioned have had a hallucinatory experience at one time or another during their lives (3).

Hallucinations occurring in sane persons are usually visual experiences, or at least predominantly so. The person having the experience often becomes aware of the presence and actual appearance of another person, usually someone known to the percipient who, unknown to him, is undergoing a crisis somewhere else. Very commonly the person of the "apparition" is dying or has just died. Sometimes the percipient becomes aware of particular details of the manner of the death or of other aspects of the dying person's situation, such as unusual clothes he may be wearing. Experiences of this type suggest, at a minimum, some kind of telepathy between the dying person and the percipient, who "sees" his apparition.

Apparitions were reported abundantly to the psychical researchers (now usually called parapsychologists) of the last quarter of the nineteenth century. Then reports of them diminished, a fact that was noted by Tyrrell in his masterly review of the subject in 1953 (4). The decreasing number of reports of apparitions caused some discredit of the older accounts. The question was asked: "If these things happened as reported in the past, why do we not have accounts of similar experiences today?" The answer, at least for the average psychiatrist, seems to be: "Because you have frightened people into thinking that they must be mad if they have a hallucinatory experience, and so they do not confide in you anymore."

Andrew MacKenzie is a journalist in London and a part-time investigator of spontaneous cases in the field of parapsychology. He is a member of the council of the esteemed Society for Psychical Research, the oldest of the scientific groups studying these and related phenomena. In *Apparitions and Ghosts* Mr. MacKenzie has provided an account of 97 apparitional experiences he has personally learned about. He has investigated the cases with different depths of inquiry. For some he has had extensive interviews with informants and has taken signed depositions, and he reports some of these cases in much detail. Others he summarizes more briefly.

Mr. MacKenzie touches on theory and interpretations, but he does not become embroiled in controversy over them. His purpose has been mainly to report a new series of apparitional experiences with, in many cases, corroborating testimony concerning both the perception and the related events, of which the percipient became aware in his vision. Many of the cases reported in this book are recent and therefore support the explanation offered earlier as to why we have fewer reports than previously of hallucinations among the sane. People continue to have these experiences and probably have them just as frequently now as at any time in the past.

If, during the past 40 years or so, the persons having these experiences did not find it worthwhile to tell other persons (especially psychiatrists) about them, that was perhaps our fault, not theirs. At least I know from my own experience that, if one is ready to hear about such experiences, one can. I have listened to, or otherwise received, reports of about 40 apparitions presented by apparently reliable informants. The ones I have investigated have, in general, features quite similar to those Mr. MacKenzie describes. This book should help psychiatrists to become more open-minded and therefore more acceptable confidants when patients (or other persons) want to describe unusu-

al experiences. And the careful study of larger numbers of cases will provide a firmer basis for the interpretation of individual cases.

Organizing the Community To Prevent Suicide, *edited by Jack Zusman, M.D., and David L. Davidson, M.D. Springfield, Ill., Charles C Thomas, 1971, 93 pp., $6.25.*

This brief but interesting book is a summation of presentations given at a workshop on suicidology held in Buffalo, N.Y., in 1968. Data about suicide are reviewed, as are the experiences of the participants, who have been leaders in setting up and running suicide and crisis centers and in training professionals and nonprofessionals in such programs.

Of note is Small and Opler's report of MacAuley's study on suicide and social integration in Buffalo (covering the years 1930 to 1954). As expected, suicides occurred more frequently in disorganized central districts, where social isolation is most marked. An unexpected finding was the higher suicide rate among white females then white males during the Depression, World War II, and the Korean War, with the inference that the signficant factor was the female's shift from maternal and homemaking roles to wartime or other employment. If this conclusion is valid, then one would expect a higher suicide rate among females in the future, as the employment and marital roles of women change in accord with current social trends. MacAuley found that the highest female suicide rate was among middle-aged married women who, in contrast to the traditional suicidal methods used by women, displayed more aggressivity by hanging themselves. The suicide rate was also striking among men in patriarchal-authoritarian families of middle-European background and of precarious social and economic status.

Shneidman reviews the rapid growth of suicide prevention programs from nine in 1964 to more than 100 in 1968, with a concurrent explosion of information on suicide. He estimates that there are at least 50,000 suicides a year, with at least 400,000 attempts. In addition to prevention and intervention, he discusses "postvention"—dealing with the bereaved families of the persons who commit suicide as well as with the further care and handling of the unsuccessful suicide attempter.

Various workshop participants discuss the establishment of suicide prevention programs, the use of volunteers and trained laymen, the squabbles among the professionals, and the concept of the suicide prevention center in relation to the crisis center and the broad-based community mental health center.

Zusman favors the ultimate demise of suicide prevention centers by incorporating their functions into more relevant and global community-oriented mental health programs. Limitations of money, professional and nonprofessional personnel, and overall community resources raise an economic question as to the best use of what is available. The community approach offers a rapidly accessible first-aid station available to large numbers of people and more adaptable in terms of correlation with other social welfare agencies and care resources of all types.

A theme running through the book is the focus on suicide as part of a broader problem of crisis intervention, with an evolution from the suicide prevention center to the crisis intervention center to the community mental health center. The latter facility can comprehend the most effective and economic use of suicide prevention (and principles thereof) as taught by the considerable number of specialists of various backgrounds who now provide leadership in this field.

This low-caloric book (93 pages) comes at a price ($6.25) at which one would have hoped for more gourmet delights. The sketchiness of detail detracts from its usefulness; on the other hand, the book is very readable and can be absorbed in an hour or two. I would have preferred a more extensive discussion of some of the content, which is limited as a source of information and even more so as a manual to accomplish the goal of organizing the community to prevent suicide. Brevity may be the soul of wit, but unfortunately, it is not the sole of wit.

The Annual Survey of Psychoanalysis, vol. 10: A Comprehensive Survey of Current Psychoanalytic Theory and Practice, *edited by John Frosch, M.D., and Nathaniel Ross, M.D. New York, International Universities Press, 1972, 420 pp., $15.*

There are few fields of medicine in which the literature is more burdened with a plethora of confusing verbiage and specialized jargon than that of psychoanalysis. It is not surprising therefore that when John Frosch and a doughty, small band of collaborators undertook to publish an annual survey of the psychoanalytic literature they soon ran into mounting difficulties in their efforts to condense and summarize it. Thus the first volume, a review of the literature of 1950, did not make its appearance until 1952.

Subsequent reviews similarly took an average of two years each to prepare, despite a substantial increase in the number of collaborating editors. Consequently, the present volume, tenth in the series, and now jointly edited by Frosch and Nathaniel Ross, with an editorial board of ten psychoanalysts and the assistance of 53 contributing editors, has only gotten up to the psychoanalytic literature of 1959. This, of course, makes a mockery of the series' subtitle, which cites a comprehensive survey of "current" psychoanalytic theory and practice. At the present rate the psychoanalytic survey of 1971's literature will not appear before 1995!

One may properly raise the question, however, as to whether this actually makes very much difference. A recent article in the *Archives of General Psychiatry* (1) raised serious doubts as to whether any really valuable or original work has taken place within the context of traditional psychoanalysis in the past 30 years. Perhaps, however, that is too harsh a judgment Certainly individuals such as Hartmann, Erikson, Anna Freud, Melanie Klein, Mahler, and Spitz, among others, have had a significant impact upon classical psychoanalytic theory, although less so upon therapy. Others, such as Rado, Kardiner, Alexander, French, Horney, and Sullivan, have possibly had a greater impact upon both theory and technique, but they are generally considered to be renegades by the more traditional followers of Freud. It cannot be accidental that Frosch and Ross have not

even deigned to include the *American Journal of Psychoanalysis*—the official organ of the Horney psychoanalytic group—among the journals selected for review.

Nonetheless, the present volume, like those which have preceded it, has much that is of interest, particularly for the psychoanalytically oriented reader. Despite all of its shortcomings as a therapeutic technique, psychoanalysis as theory, and particularly as a method of investigation of unconscious processes, offers insights into human motivation, fantasy, and behavior that no other approach can match. This is not a book that one sits down to read from cover to cover, but for those with special interests in psychoanalytic theory and therapy and their applications as of 1959 to a diverse number of clinical, educational, and cultural problems, it will offer rewarding browsing. The volume is well indexed.

Recollection and Reconstruction; Reconstruction in Psychoanalysis, *edited by Bernard D. Fine, M.D., Edward D. Joseph, M.D., and Herbert F. Waldhorn, M.D. New York, International Universities Press, 1971, 128 pp., $4 (paper).*

This is the fourth in a series of monographs reporting meetings on specific topics of the Kris Study Group of the New York Psychoanalytic Institute. The first section summarizes meetings held in 1958–1959 and the second section, those held in 1960–1961.

The book begins with a brief review of the Freudian literature. Meanings are "interpreted," but conflicts, fantasies, and events are "reconstructed" (p. 63). The monograph is interesting for the way in which the clinical examples are presented and for the discussants' assumptions and ways of thought, which reflect the gradual trend toward somewhat more dynamic thinking. However, the superego is still presumed to be formed "between four to six years of age, when infantile amnesia begins" (p. 57). In addition, the remarkable appearance in the very earliest recollections of important emotional patterns of a person's life, e.g., accident-proneness, loneliness, and so forth, is not explicitly discussed, and the relevant literature is not mentioned.

The monograph makes no pretense of reaching definitive conclusions, as its purpose is clarification of current knowledge and theory for future studies. A general difference of opinion and conclusion appears between the positions of Greenacre and Kris. Greenacre holds that analysis is genetic and therefore must reconstruct traumatic experiences, while Kris's view was that the modifications and elaboration to which these experiences are subjected make simple reconstruction impossible. All agreed that genetic, dynamic, structural, and economic factors are involved, but there seems to be little attention to why an event may be traumatic for one child and not for another and to the role of reconditioning, of the corrective emotional experience, in the use of recollection and reconstruction for therapy.

The discussions are careful and thoughtful within their frame of reference.

Inside Psychotherapy, *edited by Adelaide Bry. New York, Basic Books, 1972, 162 pp., $6.95.*

This is a neat little book. On picking it up one expects to find the potpourri usually associated with books in which each chapter is written by a different author. In addition, one wonders how anyone could provide a satisfactory *überblick* of psychotherapy, as practiced by so many clinicians, in such a short volume.

As one reads the book, he is immediately impressed by Dr. Lewis Wolberg's introduction. This gem should be required reading for all beginning psychiatrists who want to know what psychotherapy is all about. Dr. Wolberg succinctly describes many different approaches and theories. He compares one with another, skillfully weaves together the approaches of different authorities when possible, pointedly suggests differences that may or may not be significant, indicates those conditions where one approach seems more likely to be successful than another, and gently depicts the limitations of therapies and therapists. He does not say that there is more than one way to skin a cat, but he makes the point so persuasively that any psychiatrist who believes that only one approach is the right one will have to reconsider his position.

If one stops after reading only the introduction, one's time has been well spent. If one continues to read the book, however, a pleasant surprise is in store. The editor recounts direct, emotionally involved interviews that she conducted with nine psychotherapists of different disciplines. This format provides much information about the conduct of the psychotherapeutic relationship and makes for stimulating and exciting reading. One feels that he is actually sitting in on the conversations between the editor and her consultants.

The consultants include Van Buren O. Hammett, M.D. (who wrote the chapter on "Psychoanalytic Therapy"), David Hart, Ph.D. ("Jungian Therapy"), Erwin Singer, Ph.D. ("Frommian Therapy"), Frederick Perls, M.D. ("Gestalt Therapy"), Joseph Wolpe, M.D. ("Behavioral Therapy"), Ross Speck, M.D. ("Family Therapy"), Ian Alger, M.D. ("Group Therapy"), Frederick Stoller, Ph.D. ("Encounter Group Therapy"), and Paul Bindrim ("Nude Marathon Therapy").

These men all extend themselves to describe their approaches. Much more than a simple descriptive overview is provided in each case. The editor has the ability to bring out, in interview format, such lively discussions of therapy and technique that it is hard to believe how much material is actually covered.

Do not read this book is you want to learn how to conduct psychotherapy. But if you want to know what psychotherapy is all about, read it. Even if you know most of the content of the book, you'll still enjoy it.

LUDWIG M. FRANK, M.D.
West Hartford, Conn.

The Interface between Psychiatry and Anthropology, *edited by Iago Galdston, M.D. New York, Brunner/Mazel, 1971, 150 pp., $7.50.*

This collection of six papers, authored and coauthored by three physicians, one biologist, and three anthropologists, is intended to promote a better understanding of the "synergic relations between anthropology and psychiatry." The former is conceived as dealing with "the short range behavioral history of man" in terms of his *Eigenwelt*, *Mitwelt*, and *Umwelt*.

E.D. Wittkower and Guy Dubreuil open the argument with a historical review of patterns of mutual borrowing from the tool

kits and approaches of each field and of some of the resulting insights into the complex cross-cultural problems of etiology, symptomatology, treatment, and prevention. While their "reflections on the interface" are useful, they are more in the nature of "an outline of the borderline area between psychiatry and cultural anthropology" (p. 20).

R.B. Edgerton examines the question of order and the fact of cultural diversity in man-made rules for adapting to the environment as a matter of central concern to the fields of both anthropology and psychiatry. Of special interest is his treatment of the ubiquitousness of human willfulness and deviance, "no matter *what* form . . . culture will take." Although phrased essentially in voluntaristic terms, his reflections on the cross-cultural evidence on the "ambiguity" or "conscious avoidance of specificity" in rules of conduct and on the "negotiability of deviant acts" are well taken. He is correct in exhorting anthropologists to study the nature of human nature more in bio-behavioral terms and psychiatrists to study all men—"not merely patients."

W. Goldschmidt attempts to demonstrate the usefulness of the Greek concept of *areté* to "the understanding of both social systems and of individual behavior." He uses this term synonymously with dominant or ideal values, e.g., "the qualities a person should ideally possess, according to the consensus of the community" (p. 58). The manner in which the landscape of "diverse forms of areté" is presented does not lend itself to an illuminating assessment of the central problem of conceptually and methodologically linking human values with motivation.

The late Ludwig von Bertalanffy is most persuasive in marshaling diverse evidence for the utility of "the system view" in the "investigation of human singularity" in the mind-body relationship. He succeeds, even if indirectly, in pointing to the locus of the interface between anthropology and psychiatry: "Concepts such as organization, goal-directedness, differentiation, development and the like . . . concerning aspects beyond the mechanistic scheme . . . can give some answer to the question of meaning, which is nothing else than connection within a whole or a system" (pp. 115–117). The many-faceted, contingent relationships between meaning and cause must be elucidated with more theoretical vigor if the two fields truly wish to join hands in the study of "disturbance of system functions of the experiencing ego" (p. 108).

S.S. Kety succinctly states the most salient findings bearing on the probable "mechanics" of the behavior of the biochemical substrates of affect and learning. His profound understanding of the subject allows him to conclude that, although "there will someday be a biochemistry of memory but hardly ever one of memories . . . it is only by an appropriate collaboration between biology and the sciences which deal with information and experience that an understanding of human behavior will be approached" (p. 137).

G.M. Carstairs' urbane observations about man's social and cultural world are an urgent invitation to liberate more scientific energy for the proper understanding of "human social intercourse" beyond the continuing scientific and technological preoccupation "with consciously perceived cognitive messages" and with the "exploitation of . . . cognitive faculties" (p. 147).

Iago Galdston is to be commended for having succeeded in putting together a readable and stimulating volume on the continuing search to transcend conceptual, technical, and professional walls that still hang between psychiatrists and anthropologists. Careful reflection on the ideas and evidence presented should move future research efforts to a deeper level of cooperation than has been attained to date.

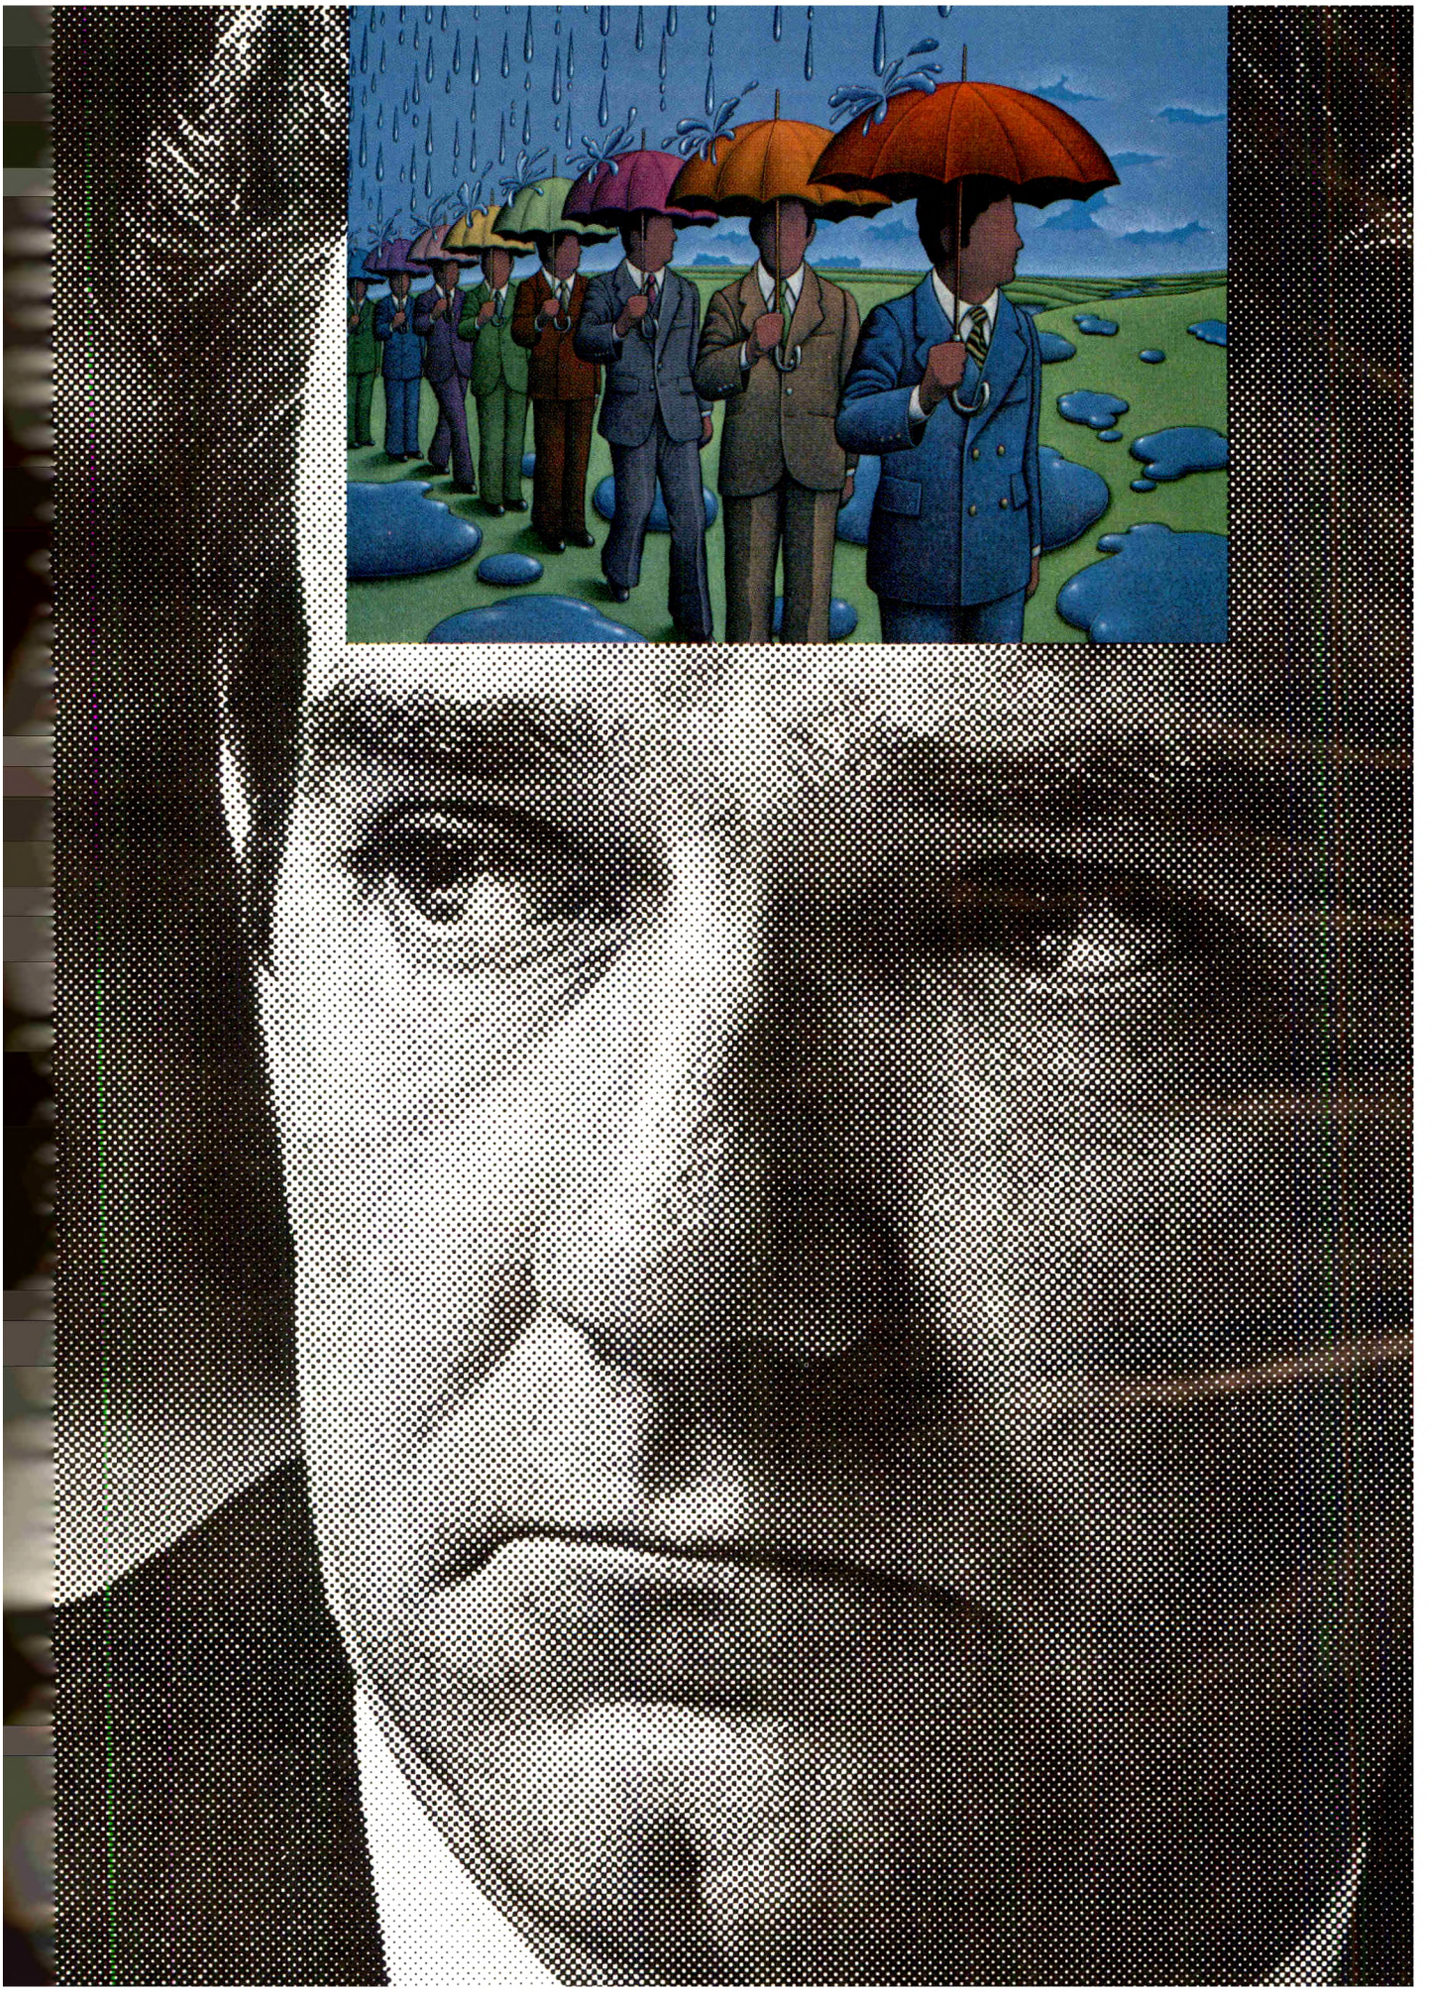
I find writing hard



When Parkinson symptoms begin to disable . . . . start

AKINETON®
(biperiden)

In early Parkinsonism, tremor and rigidity of the upper extremities are emotionally debilitating as capacity to write or for self-care are reduced. Start AKINETON early to minimize or relieve symptoms, improve function.

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

Into each life some rain must fall but George Harris expects a downpour every day.

Anxiety can be a normal response to a stressful situation. But when inappropriate anxiety becomes a way of life, medication is often indicated.

For the patient suffering from chronic neurotic anxiety, 'Stelazine' offers convenient b.i.d. dosage with no danger of habituation. And, since 'Stelazine' usually acts without sedation, people like George Harris can continue functioning while under treatment.

Stelazine®

brand of

trifluoperazine HCl

Tablets:
1 mg., 2 mg.,
5 mg., 10 mg.

in chronic neurotic anxiety*

*'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

* **Indications**

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from Smith Kline & French Laboratories, Philadelphia, Pa.

APA SELF-ASSESSMENT PROGRAM

2nd Offering of the 1972 Program

The APA offers the self-assessment test to psychiatrists, residents, and other professionals as a means to stimulate self-learning. From the test results one evaluates his own strengths and weaknesses which enable him to pursue continuing education courses to strengthen his knowledge and skills.

Already there is a trend toward establishing continuing education credits as a requirement for relicensure and renewal of membership in medical organizations. The state of New Mexico requires it for relicensure; Oregon Medical Society requires it for continuing membership. Also, the APA is considering it as a future requirement for members to continue membership.

THE PROGRAM:

- Test items stress clinical competence and cover four broad subject areas: Patient Management Problems; Problems in Diagnosis; Problems in Treatment; Problems of Current Concern to Psychiatry.
- Each participant will receive a set of "norm tables" to enable him to see how he ranks among his peers in psychiatric knowledge and skills. These tables were developed from participants' scores in the first offering of the 1972 program.
- There are NO DEADLINES—Complete the test at your leisure and score your own exam with the answer key and bibliography provided.

TAKE ACTION NOW!

Complete the application form below and mail it with your check to APA—PKSAP-11, 1700 18th St. N.W., Washington, D.C. 20009.

APPLICATION FORM—DETACH AND RETURN

I wish to participate in the self-learning program and I am a: COST

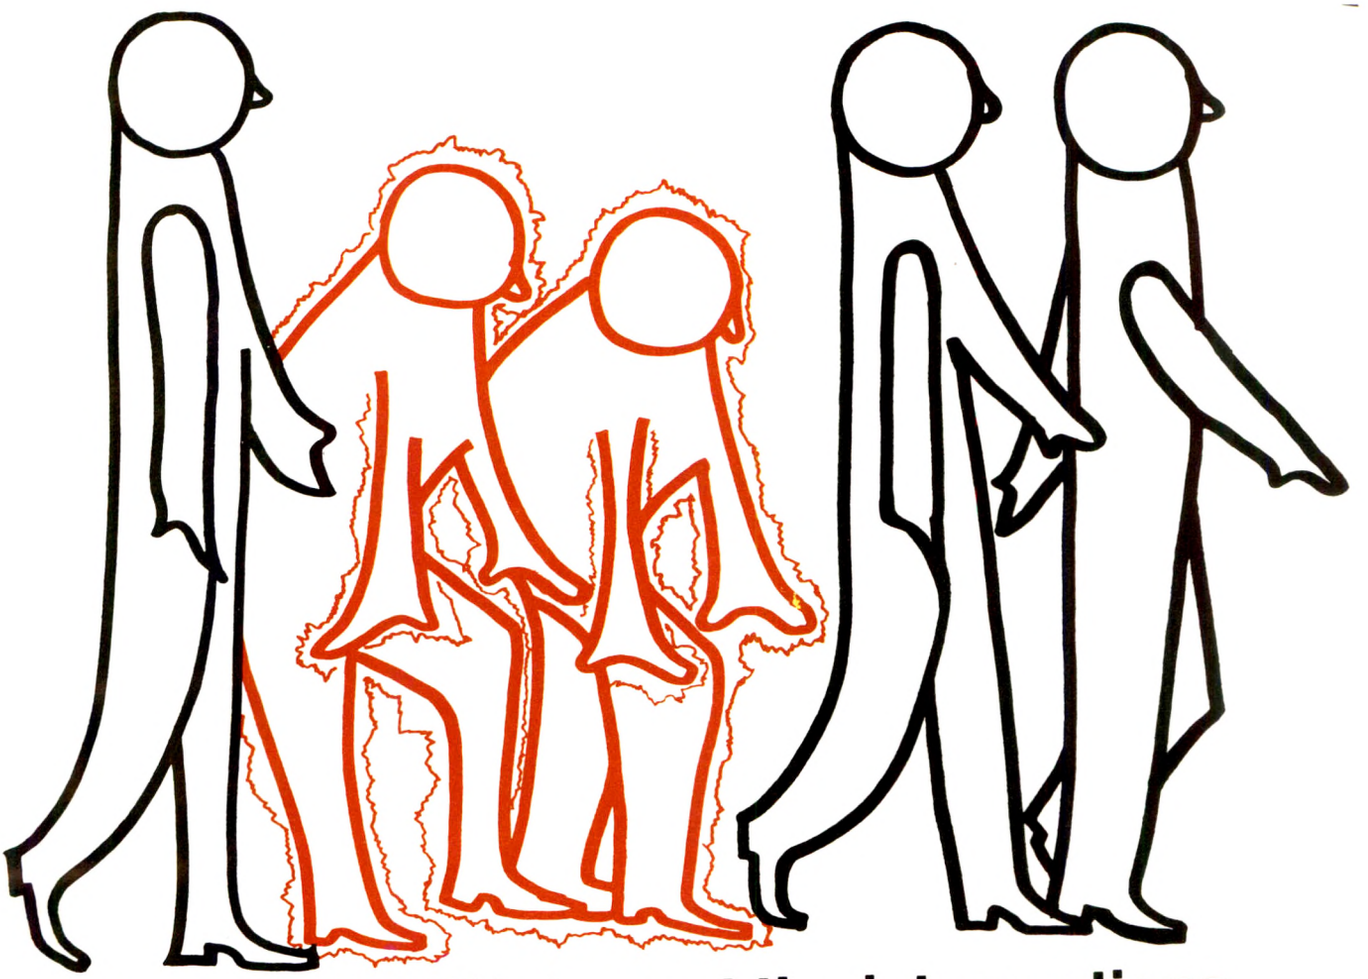
☐ Psychiatric Resident-In-Training $15.00
( ) APA, Member-In-Training
( ) Non-member, Resident-In-Training
(Psychiatric residents in training who are not APA members must submit a letter from the program director [hospital administrator] certifying resident status)

☐ Member of the American Psychiatric Association (other than above) $25.00

☐ Physician (other than above) $40.00

☐ Mental Health Professional (other than above) $40.00

Make checks payable to APA—PKSAP-II. Send application form and check to the APA, 1700 18th St., N.W., Washington, D.C. 20009. Group applications are invited, however, *the individual names must accompany the request.* PLEASE ALLOW 3 to 4 WEEKS FOR DELIVERY.



PLEASE PRINT Name and Address to which the program packet is to be shipped:

Let ARTANE interrupt the interruptions.

When phenothiazine side effects interrupt therapy, it's time for ARTANE.

Today, ARTANE is frequently the preferred agent in drug-induced parkinsonism.* It has demonstrated its ability to prevent or control extrapyramidal reactions for over two decades.

But that's just one reason why it's among the most widely used agents of its kind.

ARTANE is economical.

And it's available as tablets of 2 mg and 5 mg, elixir 2 mg/5cc† and SEQUELS® Sustained Release Capsules 5 mg each. SEQUELS provide convenience, smooth clinical response and minimal nocturnal stimulation.

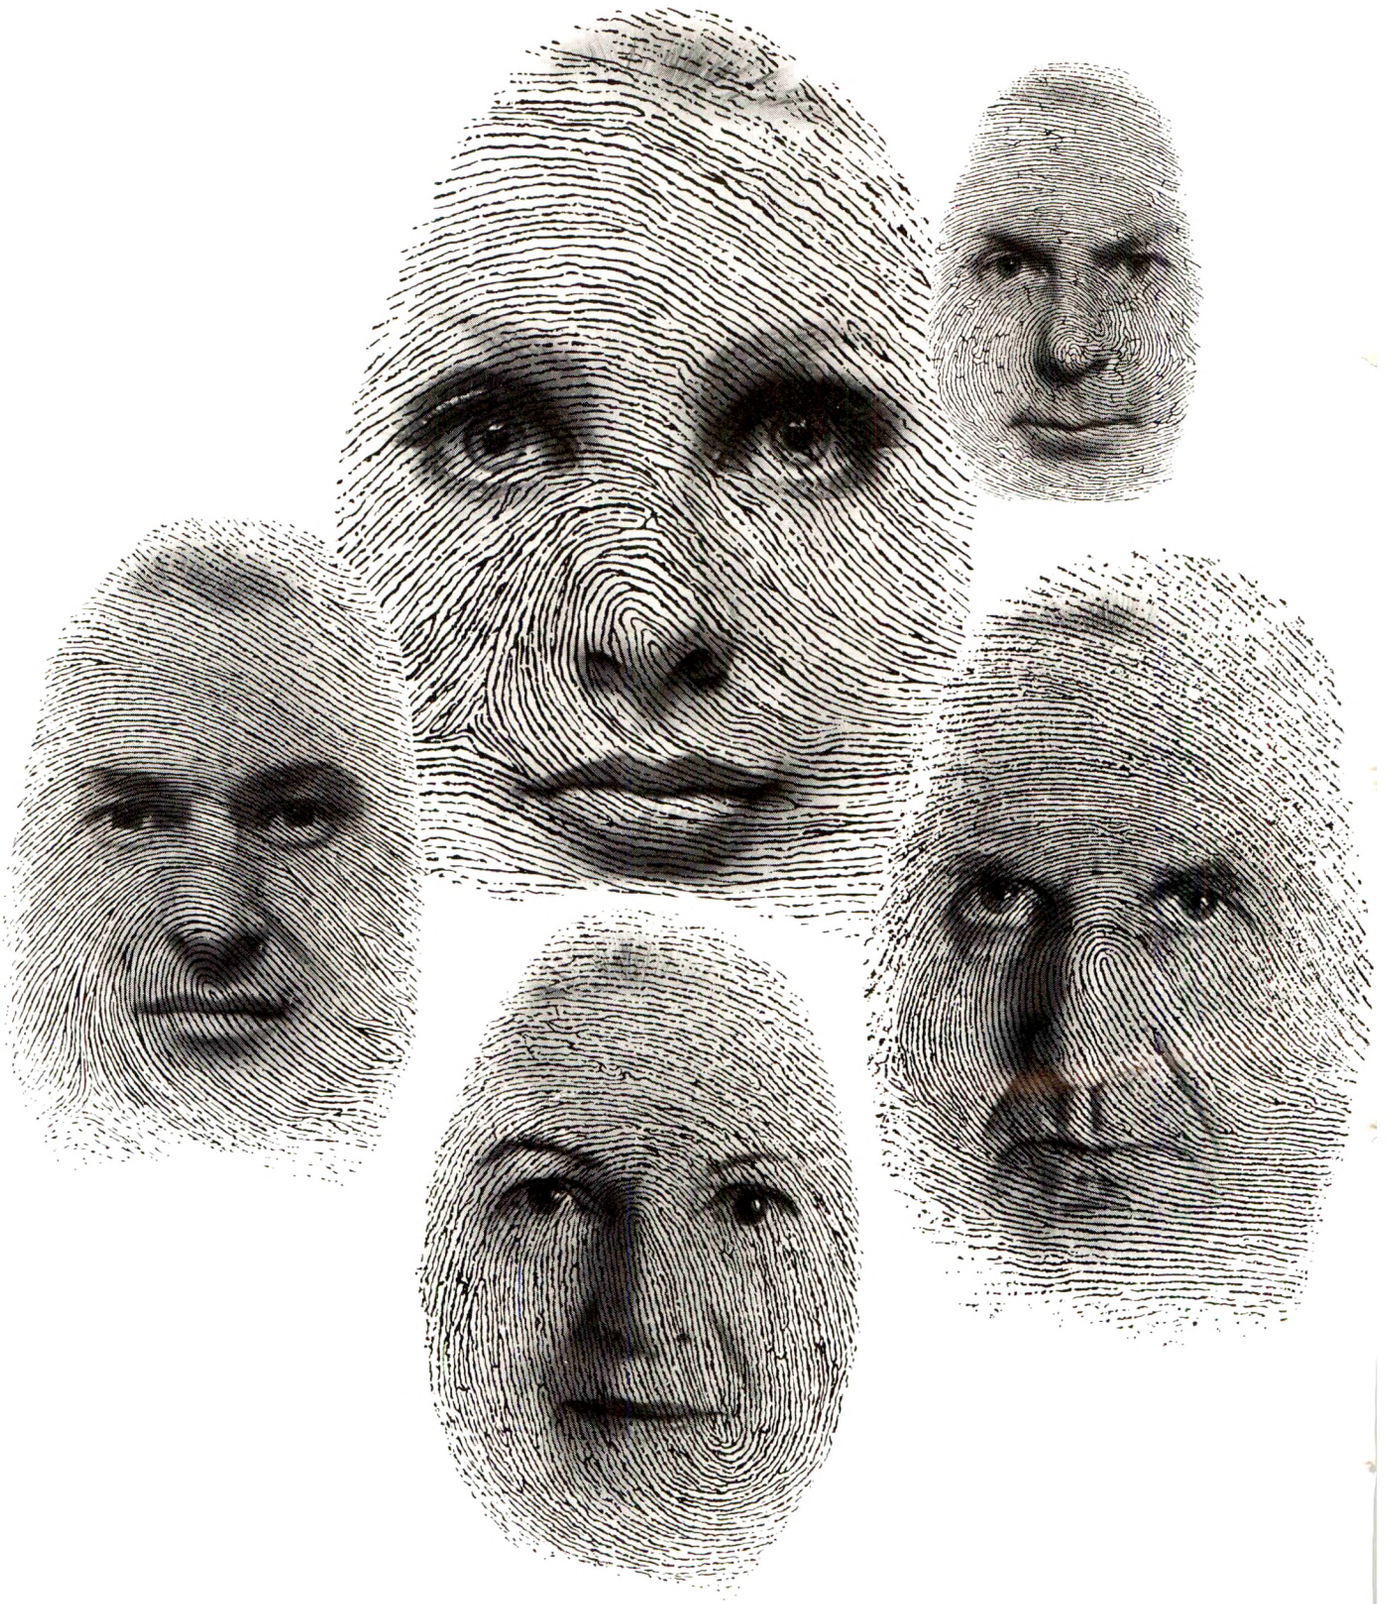
***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for the use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilatation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

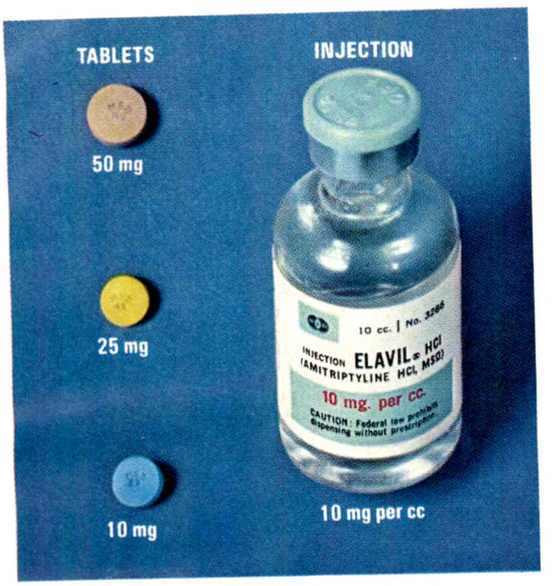
†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

THE THERAPEUTIC STANDARD



ARTANE®

TRIHEXYPHENIDYL HCl



Lederle LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York 10965

185-2

No two depressed patients are exactly alike..

...but for many patients with clinically significant depression you'll find a useful dosage form of

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

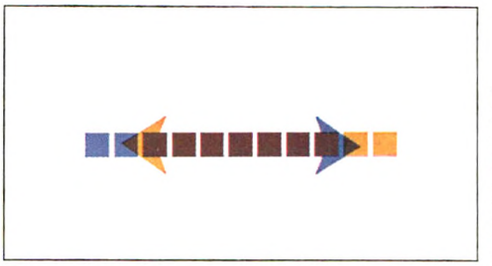
NOTE: Not recommended during the acute recovery phase following myocardial infarction. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Concurrent electroshock therapy may increase the hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue the drug several days before elective surgery if possible. Should not be given to patients who have received an MAOI within two weeks.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction or for patients under 12 years of age.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.
When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.



Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

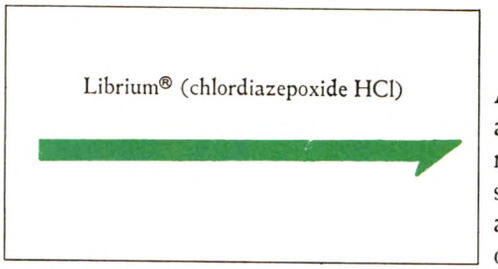
MERCK SHARP & DOHME

To reduce obstructive anxiety during therapy, expediting verbal communication

Verbal communication may be prevented or obstructed during psychotherapy by a buildup of extreme anxiety in the psychoneurotic patient as sensitive material is probed. In turn, the therapeutic impasse can generate further patient anxiety and tension. In such cases, the reduction of intense anxiety with the help of Librium (chlordiazepoxide HCl) usually facilitates verbal exchange, thereby permitting psychotherapy to proceed. Librium is prescribed by psychiatrists as adjunctive therapy because it has been found to make anxiety-blocked patients more amenable to psychotherapy. Moreover, for patients incapacitated by excessive anxiety, the action of Librium (chlordiazepoxide HCl) often favors restored performance.

Many psychiatrists have found that

Before prescribing, please consult complete product information, a summary of which follows:



Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement,

Librium® (chlordiazepoxide HCl) the calming catalyst

Librium 25 mg, given *t.i.d.* or *q.i.d.*, is particularly suitable for the relief of severe anxiety. An additional advantage is that, after more than 12 years of wide clinical use, Librium continues to demonstrate an impressive record of safety. In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated.

As with all CNS-acting agents, patients receiving Librium should be cautioned against hazardous occupations requiring complete mental alertness, such as operating machinery or driving a motor vehicle. When excessive anxiety has been reduced to appropriate levels, Librium therapy should be discontinued.

for severe anxiety
Librium® 25 mg (chlordiazepoxide HCl)
1 capsule t.i.d./q.i.d.

stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

For graduate student
John R., lying down
to sleep was a real
eye-opener.
11
12
1

Meet John R., age 33.
B.A., *cum laude*
Ph.D. in the making.

But until recently, it looked as if he might not make it. His problem: insomnia. Clinically confirmed. Unwanted wakefulness every night. It was wreaking havoc with his studies. And with his personal relationships, too.

uāālude®-300 (methaqualone) helped solve John .'s problem...but under rather unusual circum-ances.

John R. volunteered to participate...along ith nine other confirmed insomniacs...in a sleep udy[1] of experimental design, single blind, to evalu-e Quāālude-300 against a placebo. Sequentially, here were three placebo nights, followed by three rug nights, followed by four placebo nights. EEG cordings were obtained continuously from 2300 to 600 hours. He returned for a second period of 10 ays three weeks later.

Goldstein, *et al.*,[2] reported that two statis-cally significant benefits of Quāālude-300 were pparent in this particular study.

Time needed for the insomniacs to fall asleep *was reduced.*

Intermittent periods of wakefulness...so common among insomniacs...*were shorter* when Quāālude was used.

Other clinical studies, plus experience in edical practice throughout the world, have estab-shed the therapeutic value of non-barbiturate ethaqualone: Quāālude can induce sleep in 10 to 0 minutes; it usually helps produce 6 to 8 hours restful sleep; Quāālude patients usually awaken asily and without evidence of "hangover."

Side effects reported have been mild, tran-ent, and have often proved to be statistically significant when compared to placebo effects. sychological dependence occasionally occurs, hysical dependence rarely reported. (See Brief ummary of Prescribing Information.)

Maybe your patients can benefit as John R. d, by your prescribing Quāālude.

Brief Summary of Prescribing Information

Indications: Sleep. Daytime sedation.

Usual Adult Dose: *For sleep,* 150-300 mg. at bedtime. For patients previously on other hypnotics, 300 mg. for five to seven nights. *For sedation,* 75 mg. t.i.d. or q.i.d. Not recommended in children. Dosage should be individualized for aged, debilitated or highly agitated patients.

Overdosage: Acute overdosage may result in delirium and coma, with restlessness and hypertonia, progressing to convulsions. Evacuate gastric contents, maintain adequate ventilation and support blood pressure, if necessary. Dialysis may be helpful. Analeptics are contraindicated. Succinylcholine accompanied by assisted respiration has been proposed for prolonged convulsions. Overdoses of methaqualone appear to be less often associated with cardiac or respiratory depression than are overdoses of oral barbiturates, but shock and respiratory arrest may occasionally occur.

Contraindications: Contraindicated in women who are or may become pregnant; or patients with known hypersensitivity.

Warnings: Take hypnotic dose only at bedtime. Not recommended in children. Warn patient on Quāālude® (methaqualone) against driving a car or operating dangerous machinery. Care needed when administered with other sedatives, analgesic or psychotropic drugs or alcohol because of possible additive effects. Pending longer clinical experience, Quāālude should not be used continuously for periods exceeding three months. *Psychological dependence* occasionally occurs. *Physical dependence* rarely reported. However, caution needed with addiction-prone patients.

Precautions: Use with caution and prescribe small quantities in patients with anxiety states where impending depression or suicidal tendencies exist. Give in reduced doses, if at all, in patients with impaired hepatic function.

Adverse Reactions: *Neuropsychiatric:* headache, hangover, fatigue, dizziness, torpor, transient paresthesia of the extremities. An occasional patient has experienced restlessness or anxiety. *Hematologic:* aplastic anemia possibly related to methaqualone has been very rarely reported. *Gastrointestinal:* dry mouth, anorexia, nausea, emesis, epigastric discomfort, diarrhea. *Dermatologic:* diaphoresis, bromhidrosis, exanthema. Urticaria has been particularly well documented.

Supplied: Quāālude-150 (150 mg. white, scored tablets). Quāālude-300 (300 mg. white, scored tablets).

Consult complete literature before prescribing.

New APA publications—

HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST

AUTHORS: Louis S. Reed, Ph.D., Evelyn S. Myers, Patricia L. Scheidemandel

Those who hedge on granting the mentally ill adequate and equitable coverage under any national health insurance system have done so mainly on the ground that it would bankrupt the system. This book shows that this is not so. The most comprehensive study of the utilization and cost of care for mental disorders under health insurance ever undertaken, it gives facts and figures on more than 40 private health insurance plans or organizations, Medicare, other public programs in this country, and Canadian programs of hospital and medical service insurance. A wealth of data on inpatient care, in-hospital physicians' services, and ambulatory care is provided.

412 pages casebound $6.50
(2-6 copies, $6.00 ea.; 7-12 copies, $5.50 ea.; price for larger quantities supplied upon request)

EQUAL COVERAGE FOR THE MENTALLY ILL

The position statement of the American Psychiatric Association on the specifics of coverage of mental disorders under a National Health Insurance Program.

psychotic patient...

Cooperation

often attained more quickly through the rapid control of psychomotor agitation offered by

Haldol®
(HALOPERIDOL)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport in establishing the therapeutic alliance

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injectable for psychiatric emergencies: 5 mg. per cc. with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

Thorazine®

brand of

chlorpromazine

Tablets: 25 mg. of the HCl

A Sound Basis for Productive Psychotherapy

for control of agitation and anxiety
as seen in psychotic states

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders.

Probably effective: For control of the manifestations of manic-depressive illness (manic phase). For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasias, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver, or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

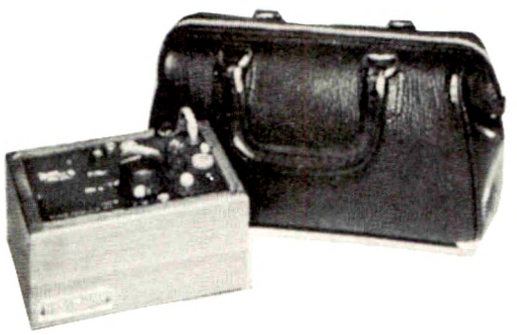
SK&F

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

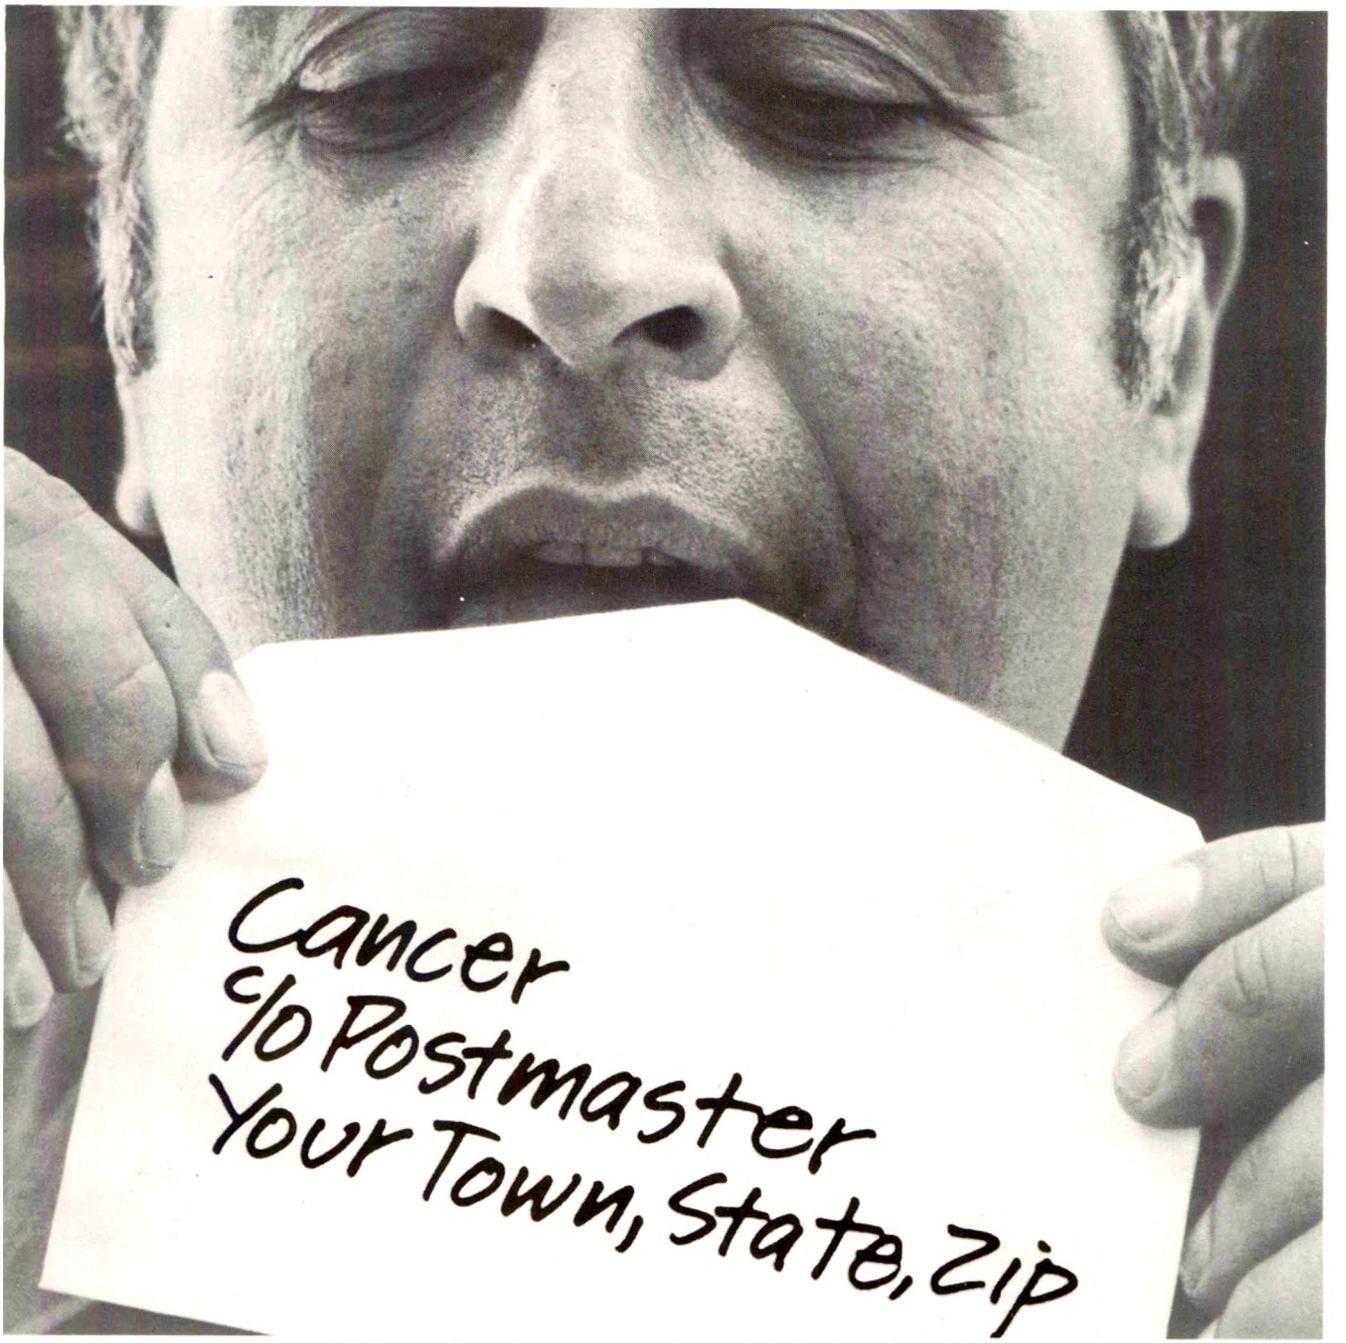
Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.



Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

Three new JIS publications:

THE TREATMENT OF DRUG ABUSE — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Jerome H. Jaffe, James N. Sussex, John Ball, Leon Brill

What can a community that wants to do something about a perceived drug abuse problem reasonably expect to get for its efforts? That is the question the authors undertook to answer through a field study that consisted of visits to nine programs operating more than forty facilities and components for various categories of persons who use drugs — mainly narcotics. They conclude that no single one of the presently available approaches can be expected to be successful with more than a small percentage of the drug-abusing population, and all approaches combined will have an "undoubtedly limited" effect. Rather than take a position for or against any particular treatment approach, they discuss the positive and negative features of each. A wealth of significant detail is provided about a number of well-known programs, with an objectivity that has been altogether too rare in this field. The authors set forth one reasonable sequence that might be followed by communities seeking to establish various drug treatment resources that will be appropriate for their particular needs.

250 pages $7.00

CHILDREN AND MENTAL HEALTH CENTERS — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Michael Fishman, Meyer Sonis

This tenth in a series of Joint Information Service field studies of mental health programs focuses on the efforts of federally assisted mental health centers to meet the needs of children and adolescents, both through direct treatment services and through consultation programs that seek to enhance the competence of numerous kinds of persons who have an important influence on the lives of children. Based on visits by the authors and consultants to eight outstanding programs, this volume also incorporates the findings of a questionnaire survey to all federally supported community mental health centers. It also provides a full but concise history of treatment efforts for young people in this country, and, most important, it sets forth a hypothetical comprehensive program that is broader than any single program presently operating in the United States.

257 pages $7.00

ELEVEN INDICES

PREPARED BY Charles Kanno

This "aid in reviewing state and local mental health and hospital programs" is a successor to the long-established *Fifteen Indices*, published by the Joint Information Service since 1956. The new version eliminates some of the indices that are no longer applicable in view of changes in the mental health delivery system, adds new ones, and uses a different reporting form for others. It provides state-by-state data for expenditures for mental health programs, hospitalization rates, rehabilitated mental illness clients, percent of population living in community mental health center catchment areas, and so on. In addition, a separate profile is provided for each state, indicating its performance against the national averages.

Books for your professional library

1. MODERN PSYCHIATRIC TREATMENT

By Thomas P. Detre, M.D., F.A.P.A.; and Henry G. Jarecki, M.D.

This practice-centered guide presents an overall orientation for evaluating psychiatric illnesses and assessing treatment response. Modern therapies, both somatic and psychological, are surveyed in detail. Helpful information includes cognitive changes in early schizophrenia, the antisocial personality, identification of potential delinquents and drug users. Emphasis is on differential diagnosis and practical recommendations.

733 pages / 30 page color section of psychotropic drugs
1971 / $25.00

2. HAZARDS OF MEDICATION

A Manual on Drug Interactions, Incompatibilities, Contraindications and Adverse Effects

By Eric W. Martin, Ph.D. Editors: Stewart F. Alexander, M.D.; William E. Hassan, Jr., Ph.D., LL.B.; Donald J. Farage, LL.D. Associate Editor: Ruth D. Martin

This important book is the first to spell out so comprehensively—at all levels from manufacture to administration—the potential dangers to patients from modern drugs. More than 400 pages of tables on drug interactions and on drug interference with laboratory tests are printed on tinted paper for quick reference. Separate monographs deal with adverse drug reactions.

895 pages / illustrated, tables and charts / 1971 / $27.50

3. THE VOICE AND ITS DISORDERS

By Margaret C. L. Greene, F.C.S.T.

This is the updated edition of what is widely regarded as the best, single reference on the physics, anatomy, physiology and treatment of the voice mechanism, by one of the world's leading authorities on voice and speech therapy. Both the normal voice and voice disorders are covered in depth. The etiology, symptoms, therapy and rehabilitation for each voice disorder is presented fully. New material includes: the problem of and therapy for voice strain and abuse; reappraisal of hysterical voice disorders in the light of present thinking on anxiety states and psychosomatic medicine; effects of psychiatric drugs on laryngeal function.

461 pages / 47 illustrations / 3rd Edition, 1972 / $19.00

4. ILLUSTRATED MANUAL OF NEUROLOGIC DIAGNOSIS

By R. Douglas Collins, M.D.

Clearer recognition and understanding of neurological disorders is offered the reader through this book's use of ingenious three-dimensional, full-color illustrations and coordinated text. Basic neurologic principles and symptomatology are outlined, typical case histories with broad clinical application are presented, and possible modes of treatment are summarized.

177 pages / 164 illustrations (108 in color) / 1962 / $15.00

Help the alcoholic get out of the bottle with

ANTABUSE®

BRAND OF DISULFIRAM

A STRONG DETERRENT FOR THE ALCOHOLIC WHO DOESN'T WANT TO DRINK

The medical need

Nine million patients in the U.S. need help. They suffer from a disease injurious to their health and to a sense of security in family, job, and community. This disease is also responsible for a high toll in death and injury on the highway. Yet alcoholism, the number one drug abuse problem in the U.S. today, is a relatively controllable disease.

Early detection and treatment

Often, you may see an alcoholic patient under another guise. His presenting symptoms or complaints—such as G.I. disorders, circulatory problems, or an accident—do not immediately reveal his alcoholism. Many patients prefer not to tell you about their drinking problem. Women, in particular, tend to be more secretive and solitary about their drinking. Generalized complaints such as insomnia, headache, depression may offer the first clues in the early detection of alcoholism.

Three steps forward

While the etiology of alcoholism remains complex and largely undetermined, the essential therapeutic measure is to stop the alcoholic from drinking. ANTABUSE (disulfiram) can help you help the motivated alcoholic get "out of the bottle." If the patient has a sincere desire to stop drinking, but the usual "faltering will," ANTABUSE can help to shore up his resolve.

The first step is his agreement to accept supportive drug therapy with ANTABUSE to deter him from drinking. The second step is the decision the patient must make each day to take his alcohol-deterrent medicine. The third step is the maintenance of sobriety with ANTABUSE (disulfiram), allowing him to cooperate in other aspects of a total treatment plan.

No chance of cross addiction

ANTABUSE has been used effectively as a medical adjunct in the control of alcoholism for more than 20 years. Unlike tranquilizers and sedatives, it is nonhabituating, so that there is no chance of cross addiction. It is important, however, to give the patient a clear and detailed description of the effects of ingesting alcohol after he has taken ANTABUSE (even up to 14 days after the last dose of ANTABUSE)...and how this becomes a psychologic benefit in that it deters drinking and helps to enforce sobriety.

Ayerst Laboratories, makers of ANTABUSE, will be pleased to send you further information and patient aids to help you in the management of the alcoholic patient.

Simply fill out the coupon and mail.

(See next page of advertisement for Brief Summary.)

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE®
(DISULFIRAM)
In Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS

ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acne-form eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, it should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokaliemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

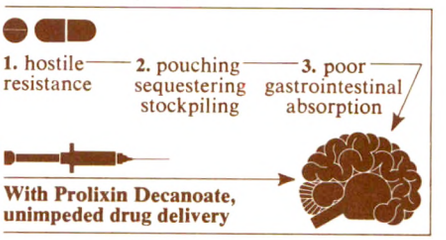
Controlled Drug Delivery

with new

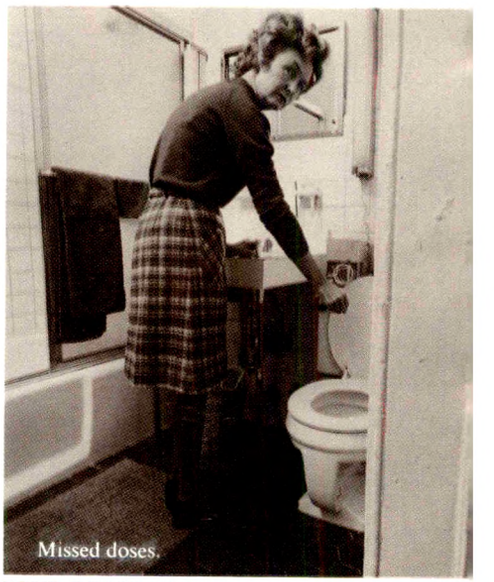
PROLIXIN® DECANOATE



FLUPHENAZINE DECANOATE INJECTION)

Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer with an average duration of effect of about 2 weeks

Controlled drug delivery — a revolution in patient management

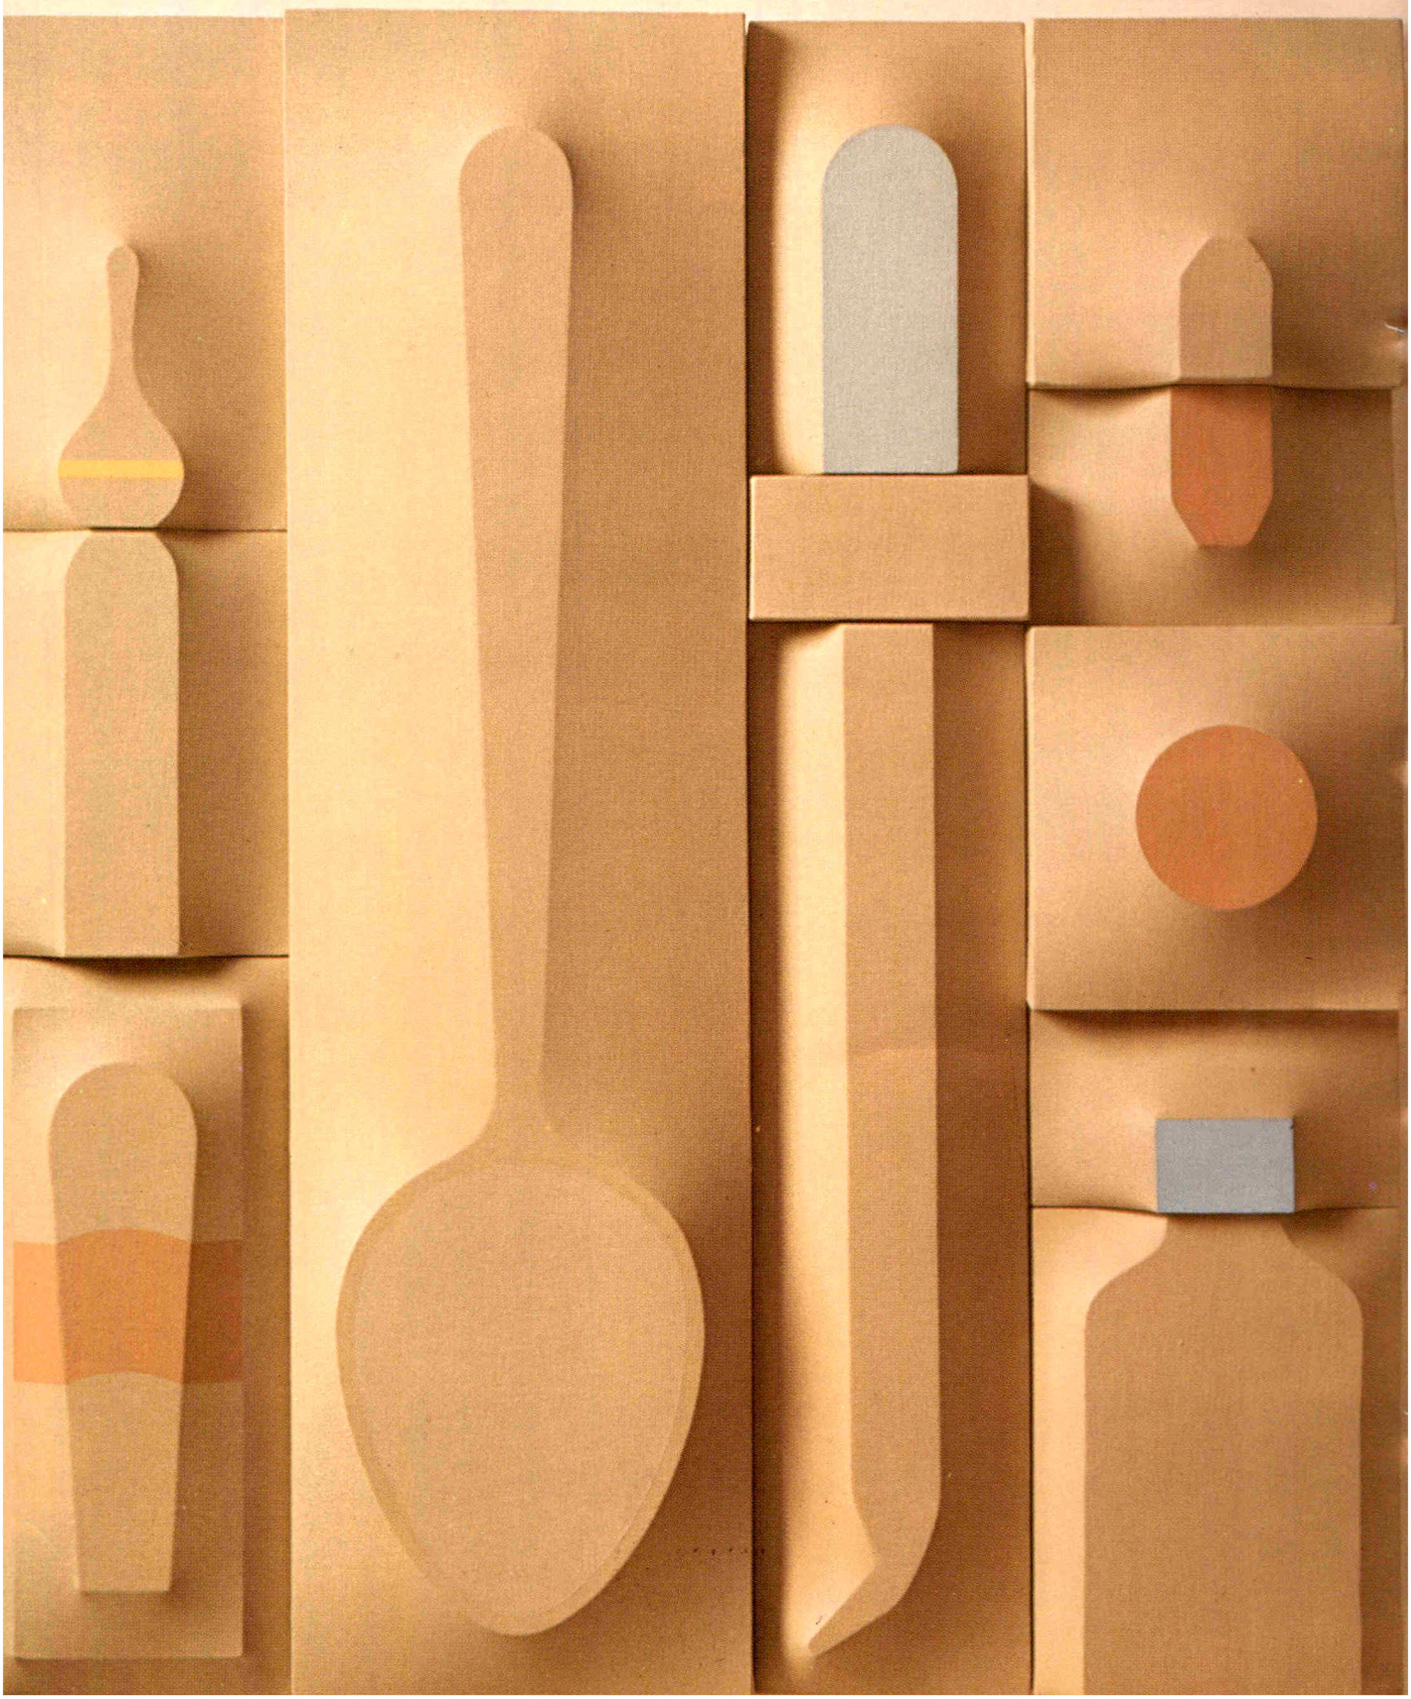


PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ASSURE EFFECTIVE, UNHINDERED MEDICATION

Controlled drug delivery is *physician*-controlled delivery, an effective prophylactic maneuver against disruption of therapy—one of the most common causes of psychotic relapse. Is the patient taking his medication? You know because you administer it or direct others to. Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

In most patients, symptomatology is controlled by Prolixin Decanoate for periods of two weeks with a single injection. Sequestered medication and similar problems associated with oral therapy are not encountered. Nor does the patient risk drug loss through severe diarrhea or poor gastrointestinal absorption. Prolixin Decanoate keeps the patient medicated...helps make him more amenable to the entire treatment program and improves his chances for rehabilitation and discharge.

The outpatient is vulnerable to the dictates of his own poor judgment. Deluded by a sense of well-being, he may question the need for medication. Family and friends often give him misleading advice. Oral therapy in such a patient encourages missed doses. Medication with Prolixin Decanoate (Fluphenazine Decanoate Injection) helps assure drug delivery when required and in the dosage prescribed. It helps keep the outpatient out.



FOUR REASONS FOR READMISSION...

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

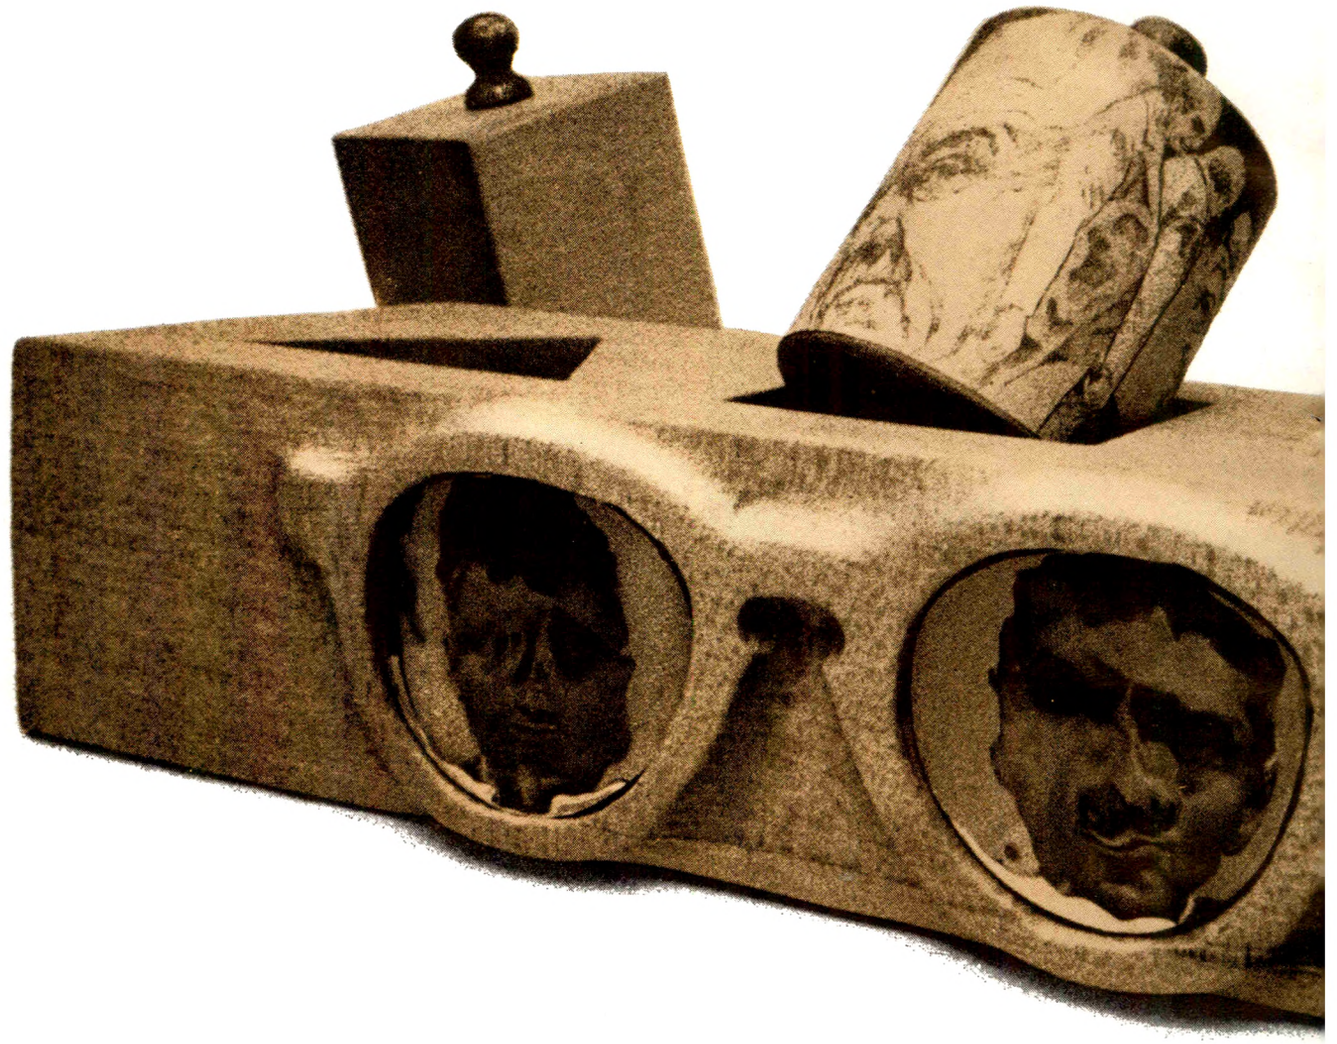
Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.



Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

Manufactured by LAKESIDE LABORATORIES
Division of Colgate-Palmolive Company

Distributed by
LAKESIDE LABORATORIES, INC.
Milwaukee, Wisconsin 53201

Help improve your depressed patients' ability to cope.

In Brief:
Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.
Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.
Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.
Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.
Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug, response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.
Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially

Controlled Drug Delivery

in schizophrenia with new

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anti-cholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of anti-parkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage. A persistent and sometimes irreversible pseudo-parkinsonian syndrome may develop with chronic administration of phenothiazine compounds. Rhythmic, stereotyped dyskinetic involuntary movements, particularly of the face, mouth, tongue and jaw occur, and may be accompanied by choreiform movements of the limbs. The symptoms persist after drug withdrawal. Anti-parkinsonian agents are seldom of benefit. The risk appears to be greatest in elderly females with organic brain damage receiving large and prolonged doses. Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

Supply: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

ability of the inpatient and help maintain him in the community are true for the patient who has never been hospitalized. It is just these advantages that will help the physician or psychiatrist keep him in the community without the need for custodial care.

Controlled drug delivery — a revolution in efficiency of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) SAVES TIME, REDUCES COST IN THE HOSPITAL, CLINIC, OFFICE

Controlled drug delivery saves time, reduces costs in the hospital. With Prolixin Decanoate there can be no palming, pouching, regurgitating. With Prolixin Decanoate resistance to therapy dwindles. With symptoms controlled, the patient is more manageable, more comfortable, more amenable to the total hospital treatment program. With Prolixin Decanoate only 1 dose visit every 1 to 3 weeks with an average of about 2 weeks is required.

Controlled drug delivery saves time, reduces costs in the clinic and office.

With Prolixin Decanoate less frequen dosing. With Prolixin Decanoate (Flu phenazine Decanoate Injection) mos patients report for their injections onl once in every 2-week period.

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients

For brief summary, see last page of this presentation.

ROLIXIN® DECANOATE
'luphenazine Decanoate Injection)
SSURES ECONOMIC DRUG
ELIVERY...LESS FREQUENT
OSING THAN WITH ORAL
HERAPY

Controlled drug delivery brings cost therapy down with less hospitaliza-ɔn, less nursing time, less frequent ɜsing. Low annual dosage means less st for the hospital, for the patient's mily, and for the community. It eans a minimum of drug holidays to oid long-term complications, with eir confusing schedules for patient ıd family.

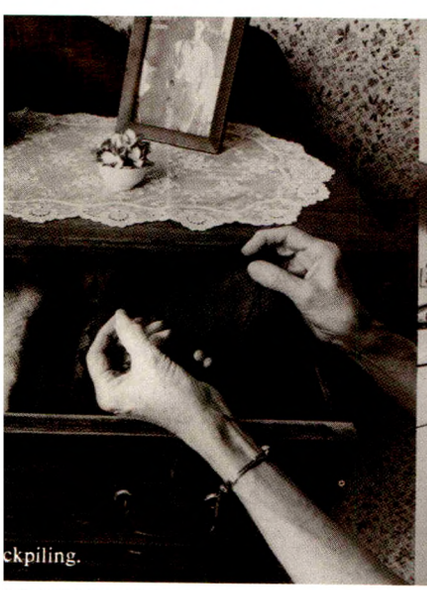
ɔntrolled drug delivery — revolution in the treatment of the hizophrenic patient

ROLIXIN® DECANOATE
luphenazine Decanoate Injection)
ELPS ENHANCE LIKELIHOOD F DISCHARGE

Optimally, the mental hospital ould be a rehabilitating bridge be-een life before and life after custo-al care. Prolixin Decanoate often ɔrtens that bridge because getting the ɔatient out is frequently a matter of eping him medicated. And 1 injec-ɔn of Prolixin Decanoate means ap-oximately 2 weeks of symptom ntrol. The importance of control by ɜ physician with this injectable can seen in the fact that about 1 out of ery 5 inpatients does not take his tab-s even when they are administered by nursing staff. With controlled drug delivery, lost or hidden doses are not a problem.

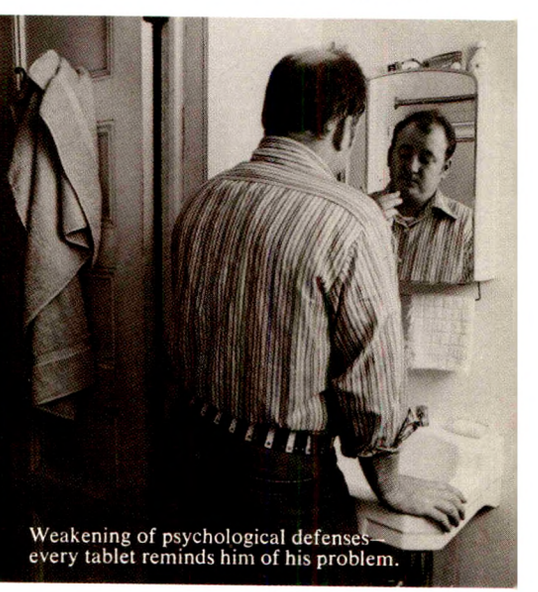
In one study,[1] 24 chronic long-term hospital patients were treated with Prolixin Decanoate in dosages of 12.5 mg. to 75 mg. given every 7 days to 3 weeks. Most of the patients received 25 to 50 mg. per injection. Of these, 13 were discharged after 6 months of treatment, 4 were considered dischargeable, and 7 did not improve. In 12 of the 24 patients who previously had been on different psychotropic drugs for periods of 4 to 96 weeks, improvement with Prolixin Decanoate (Fluphenazine Decanoate Injection) was observed in affect, volition, and higher mental functions. Dischargeability in these patients "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[1]

Controlled drug delivery — a revolution in the care of the outpatient



PROLIXIN® DECANOATE
(Fluphenazine Decanoate Injection)
PROMOTES CONTINUITY OF MEDICATION WITH DIMINISHED LIKELIHOOD OF RELAPSE COMPARED WITH ORAL THERAPY

Success in rehabilitative areas like employment and social acceptance depends in large measure on adequate and continuing phenothiazine intake; success in family adjustment no less so. Short-acting medication is not the best path to such success. According to one report,[2] "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication." And McClellan and Cowan[3] state that a substantial number of patients taking antipsychotic drugs do so in amounts significantly less than those prescribed. Even once-daily administration does not solve the problem of poor home supervision or the patient's lack of insight into his condition.



Controlled drug delivery with Prolixin Decanoate (Fluphenazine Decanoate Injection) is an efficient route to continuity of medication, and therefore to long-term remission. For one thing there is less strain on the patient's often tenuous adjustment to family living. Since family members are not responsible for supervising the patient's medical needs, they tend to be more accepting, and better feeling is promoted merely because the controlled delivery regimen demonstrates that improvement is possible. Controlled drug delivery also strengthens the patient's psychological defenses. He is not reminded of his psychiatric illness by multiple daily doses.

The same unique advantages of controlled drug delivery with Prolixin Decanoate that promote the discharge-

(Continued on following page)

ckpiling.

Misleading advice from family and friends.

Weakening of psychological defenses — every tablet reminds him of his problem.

OD REASONS FOR CONTROLLED DRUG DELIVERY

THE AMERICAN JOURNAL OF PSYCHIATRY

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

CALCUTTA

The American Journal of Psychiatry, formerly *The American Journal of Insanity*, is published monthly by the American Psychiatric Association. Editorial office: 1700 Eighteenth Street, N.W., Washington, D.C. 20009; telephone (202) 232-7878.

Subscriptions: U.S. $15.00 per year, Canada and South America $15.75, other foreign $18.00; single issues: $1.75 plus postage.

APA members should direct changes of address and communications about nonreceipt of the *Journal* to the Manpower Division, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009.

Communications from nonmember subscribers and all business communications should be directed to Mr. Robert J. Lowe, Publications Services Division, at the same address.

Advertising representatives: Steven K. Herlitz, Inc., 850 Third Avenue, New York, N.Y. 10022.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for the use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilatation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben. 0.02% propylparaben, and 5% alcohol as preservatives.

*This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

FOR YOUR STAFF:

A brief, eclectic introduction to mental illness and mental health care!

New 5th Edition!

Ulett

A Synopsis of Contemporary Psychiatry

As more types of personnel become involved in the treatment and rehabilitation of the mentally ill, this useful reference meets the need for a simplified, factual presentation of the complex field of clinical psychiatry. Carefully revised, this new edition reflects the current trend to a psychodynamic approach to mental illness. In addition to offering basic information, it clarifies recent findings concerning the use of depth electrodes in taking EEG's, and includes new material on the use of EEG's in diagnosing epilepsy. A useful table catalogs defense mechanisms.

By GEORGE A. ULETT, A.B., M.S., M.D., Ph.D., Professor and Chairman, Missouri Institute of Psychiatry (St. Louis), University of Missouri School of Medicine. July, 1972. 5th edition, 367 pages plus FM I-XIV, 4⅞" x 7⅝". Price, $10.90.

Please send me, on 30-day approval, the 5th edition of Ulett, A SYNOPSIS OF CONTEMPORARY PSYCHIATRY (#5175), priced at $10.90. I save delivery charges by enclosing payment with this order.

Withdrawn and uncommunicative?...Or responsive?

While psychotic symptoms remain acute, the barrier between you and the withdrawn, uncommunicative patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

responsiveness often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

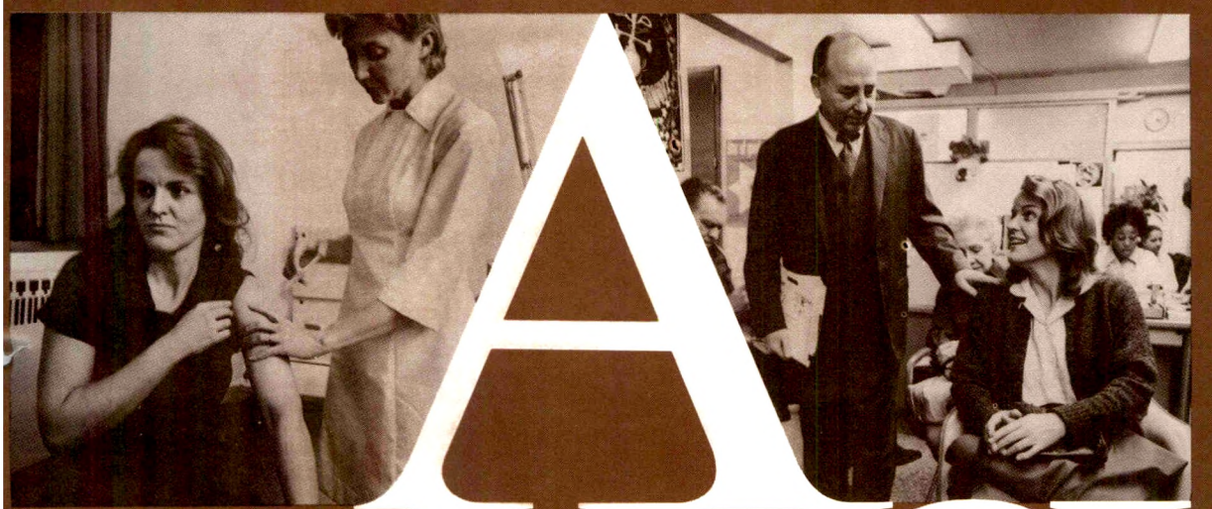
Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.



Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

McNEIL McNeil Laboratories, Inc.

For schizophrenic patients...

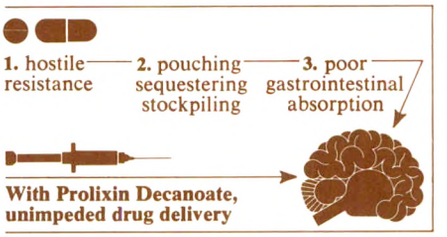
A way out:

...that helps keep them out

Controlled Drug Delivery

with new

PROLIXIN® DECANOATE



(FLUPHENAZINE DECANOATE INJECTION)

Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer with an average duration of effect of about 2 weeks

Controlled drug delivery — a revolution in patient management

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ASSURE EFFECTIVE, UNHINDERED MEDICATION

Controlled drug delivery is *physician*-controlled delivery, an effective prophylactic maneuver against disruption of therapy—one of the most common causes of psychotic relapse. Is the patient taking his medication? You know because you administer it or direct others to. Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

In most patients, symptomatology is controlled by Prolixin Decanoate for periods of two weeks with a single injection. Sequestered medication and similar problems associated with oral therapy are not encountered. Nor does the patient risk drug loss through severe diarrhea or poor gastrointestinal absorption. Prolixin Decanoate keeps the patient medicated...helps make him more amenable to the entire treatment program and improves his chances for rehabilitation and discharge.

The outpatient is vulnerable to the dictates of his own poor judgment. Deluded by a sense of well-being, he may question the need for medication. Family and friends often give him misleading advice. Oral therapy in such a patient encourages missed doses. Medication with Prolixin Decanoate (Fluphenazine Decanoate Injection) helps assure drug delivery when required and in the dosage prescribed. It helps keep the outpatient out.

Missed doses.

FOUR REASONS FOR READMISSION...

For brief summary, see last page of this presentation.

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) ASSURES ECONOMIC DRUG DELIVERY...LESS FREQUENT DOSING THAN WITH ORAL THERAPY

Controlled drug delivery brings cost of therapy down with less hospitalization, less nursing time, less frequent dosing. Low annual dosage means less cost for the hospital, for the patient's family, and for the community. It means a minimum of drug holidays to avoid long-term complications, with their confusing schedules for patient and family.

Controlled drug delivery — a revolution in the treatment of the schizophrenic patient

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ENHANCE LIKELIHOOD OF DISCHARGE

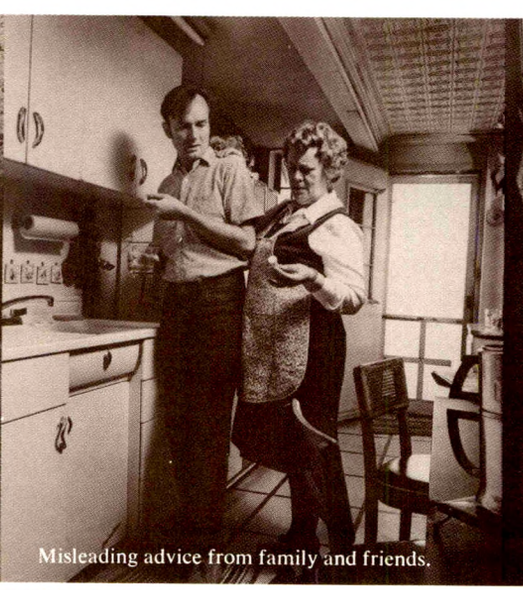
Optimally, the mental hospital should be a rehabilitating bridge between life before and life after custodial care. Prolixin Decanoate often shortens that bridge because getting the inpatient out is frequently a matter of keeping him medicated. And 1 injection of Prolixin Decanoate means approximately 2 weeks of symptom control. The importance of control by the physician with this injectable can be seen in the fact that about 1 out of every 5 inpatients does not take his tablets even when they are administered by nursing staff. With controlled drug delivery, lost or hidden doses are not a problem.

In one study,[1] 24 chronic long-term hospital patients were treated with Prolixin Decanoate in dosages of 12.5 mg. to 75 mg. given every 7 days to 3 weeks. Most of the patients received 25 to 50 mg. per injection. Of these, 13 were discharged after 6 months of treatment, 4 were considered dischargeable, and 7 did not improve. In 12 of the 24 patients who previously had been on different psychotropic drugs for periods of 4 to 96 weeks, improvement with Prolixin Decanoate (Fluphenazine Decanoate Injection) was observed in affect, volition, and higher mental functions. Dischargeability in these patients "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[1]

Controlled drug delivery — a revolution in the care of the outpatient

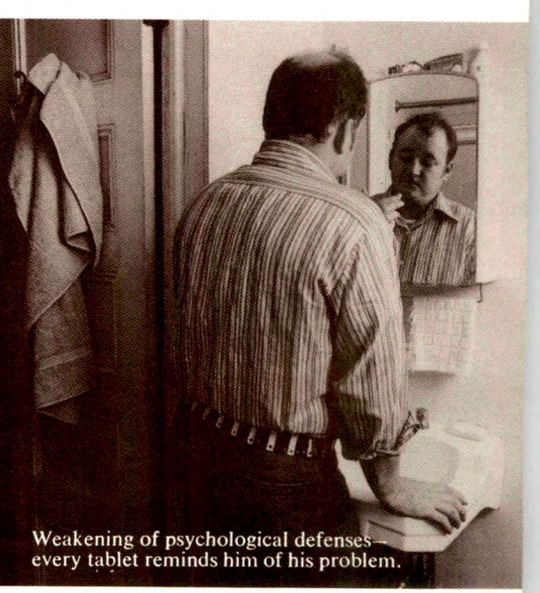
PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) PROMOTES CONTINUITY OF MEDICATION WITH DIMINISHED LIKELIHOOD OF RELAPSE COMPARED WITH ORAL THERAPY

Success in rehabilitative areas like employment and social acceptance depends in large measure on adequate and continuing phenothiazine intake; success in family adjustment no less so. Short-acting medication is not the best path to such success. According to one report,[2] "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication." And McClellan and Cowan[3] state that a substantial number of patients taking antipsychotic drugs do so in amounts significantly less than those prescribed. Even once-daily administration does not solve the problem of poor home supervision or the patient's lack of insight into his condition.



Controlled drug delivery with Prolixin Decanoate (Fluphenazine Decanoate Injection) is an efficient route to continuity of medication, and therefore to long-term remission. For one thing there is less strain on the patient's often tenuous adjustment to family living. Since family members are not responsible for supervising the patient's medical needs, they tend to be more accepting, and better feeling is promoted merely because the controlled delivery regimen demonstrates that improvement is possible. Controlled drug delivery also strengthens the patient's psychological defenses. He is not reminded of his psychiatric illness by multiple daily doses.

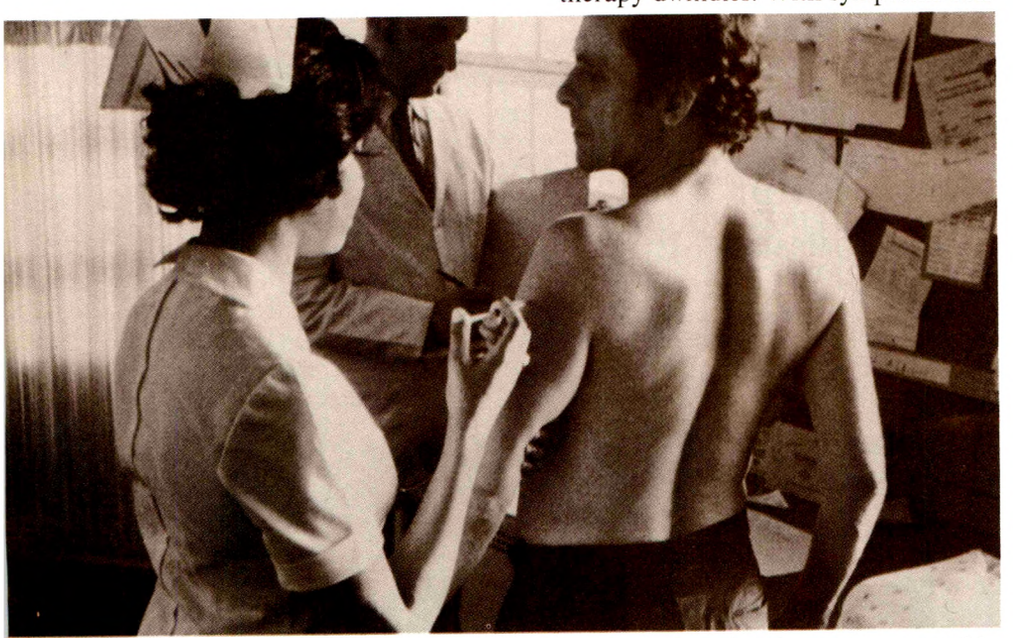
The same unique advantages of controlled drug delivery with Prolixin Decanoate that promote the discharge-



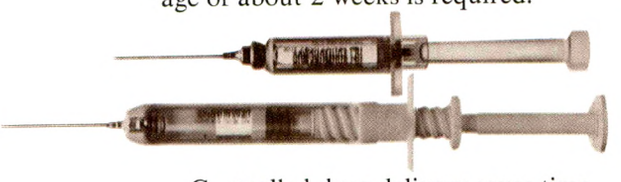
(Continued on following page)

Stockpiling.

Misleading advice from family and friends.



Weakening of psychological defenses — every tablet reminds him of his problem.



(Continued from preceding page)
ability of the inpatient and help maintain him in the community are true for the patient who has never been hospitalized. It is just these advantages that will help the physician or psychiatrist keep him in the community without the need for custodial care.

Controlled drug delivery—a revolution in efficiency of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) SAVES TIME, REDUCES COST IN THE HOSPITAL, CLINIC, OFFICE

Controlled drug delivery saves time, reduces costs in the hospital. With Prolixin Decanoate there can be no palming, pouching, regurgitating. With Prolixin Decanoate resistance to therapy dwindles. With symptoms controlled, the patient is more manageable, more comfortable, more amenable to the total hospital treatment program. With Prolixin Decanoate only 1 dose visit every 1 to 3 weeks with an average of about 2 weeks is required.

Controlled drug delivery saves time, reduces costs in the clinic and office.

With Prolixin Decanoate less frequent dosing. With Prolixin Decanoate (Fluphenazine Decanoate Injection) most patients report for their injections only once in every 2-week period.

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Controlled drug delivery—a revolution in convenience of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) MAY BE DELIVERED IN EASY-TO-USE UNIMATIC® SYRINGES

Prolixin Decanoate may be given intramuscularly or subcutaneously Local tissue reactions occur only rarely

A dry syringe and needle of at least 21 gauge should be used. Use of a wet needle or syringe may cause the solution to become cloudy. Prolixin Decanoate is available in vials of 5 cc. and in Unimatic single-dose preassembled syringes and in Unimatic cartridge needle units with a reusable-plastic holder.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances they are persistent (see Adverse Reactions section of Brief Summary) Patients should be forewarned and reassured.

Controlled Drug Delivery

in schizophrenia with new

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anti-cholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of anti-parkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage. A persistent and sometimes irreversible pseudo-parkinsonian syndrome may develop with chronic administration of phenothiazine compounds. Rhythmic, stereotyped dyskinetic involuntary movements, particularly of the face, mouth, tongue and jaw occur, and may be accompanied by choreiform movements of the limbs. The symptoms persist after drug withdrawal. Antiparkinsonian agents are seldom of benefit. The risk appears to be greatest in elderly females with organic brain damage receiving large and prolonged doses. Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

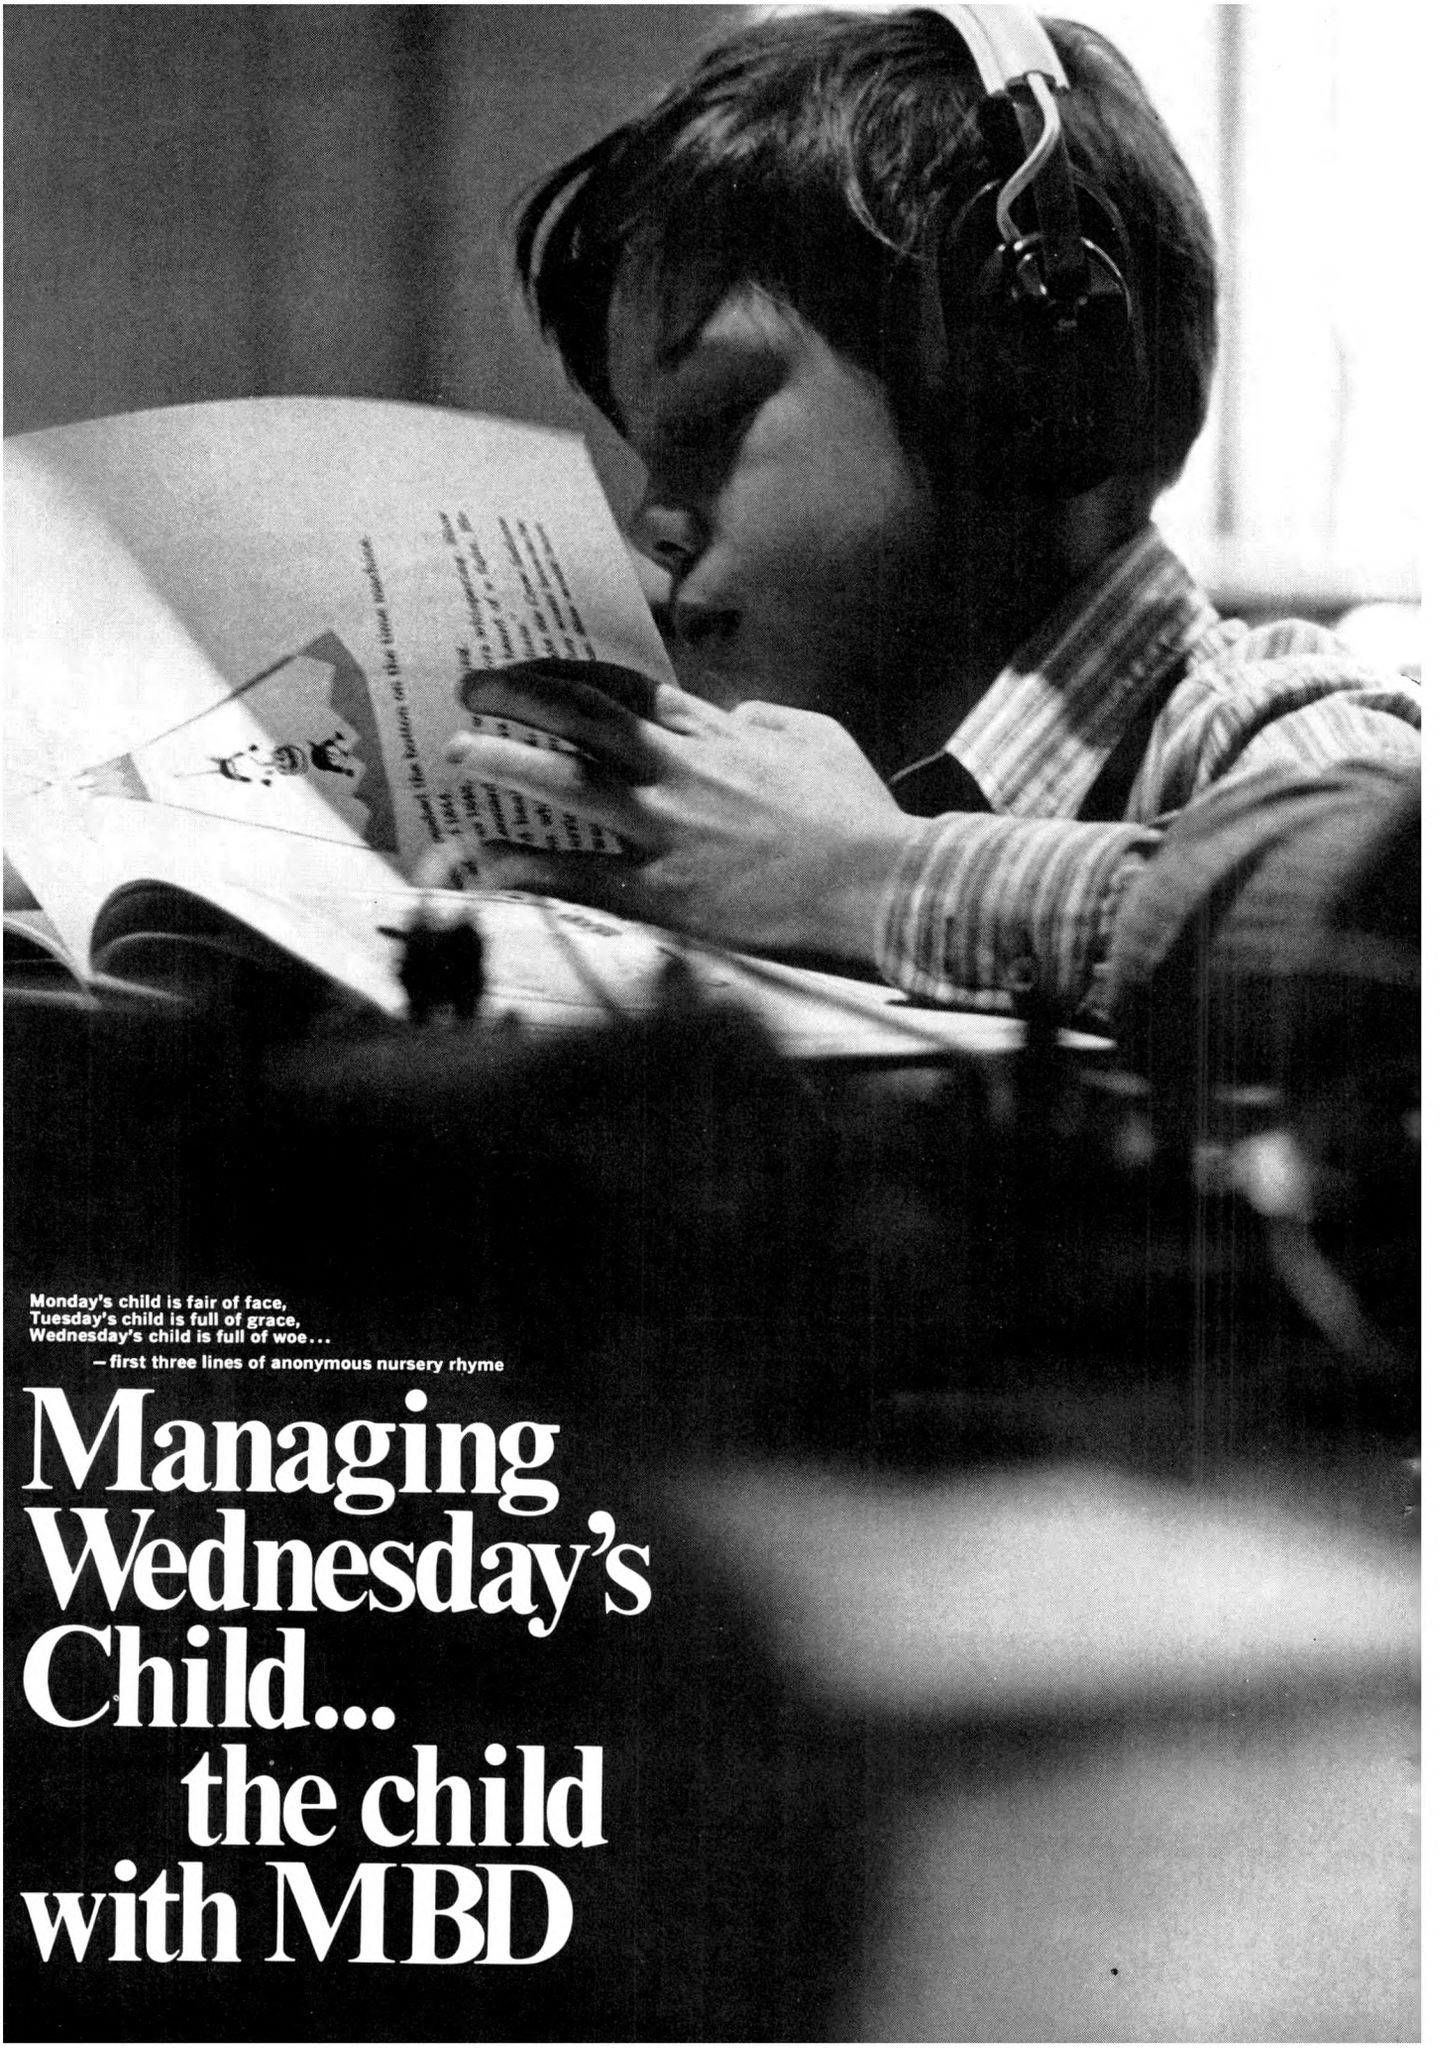
Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.



Supply: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

A15

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

– first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.

Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500. 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Ritalin®
(methylphenidate)
only when medication is indicated

CIBA

No two depressed patients are exactly alike...

..but for many patients with clinically significant depression you'll find a useful dosage form of

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

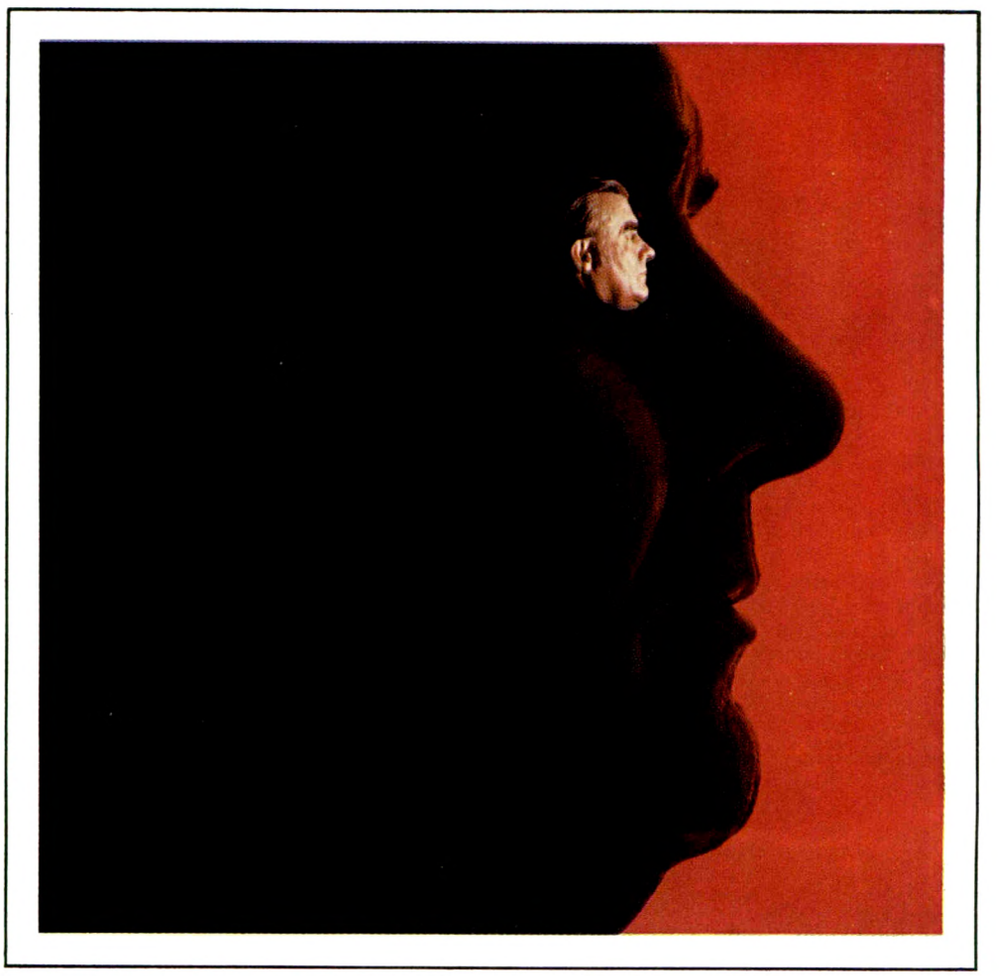
NOTE: Not recommended during the acute recovery phase following myocardial infarction. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Concurrent electroshock therapy may increase the hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue the drug several days before elective surgery if possible. Should not be given to patients who have received an MAOI within two weeks.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction or for patients under 12 years of age.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.
When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.



Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

BASIC ANXIETIES OF TODAY'S NEUROTIC PATIENT

The Inadequate Self

Low Self-Esteem... High Levels of Anxiety

When the neurotic patient thinks of himself—and he tends to be excessively introspective—his thoughts often represent an extreme self-judgment, a condemning of himself. Characteristically, the neurotic is controlled by self-defining patterns of thoughts inadequately (or pathologically) developed in childhood. (In many cases, his negative self-evaluation stems from the internalization of early parental contempt.) Now, as an adult, he still sees himself as puny, weak, ineffectual, even worthless. Moreover, he lives in a constantly changing, extraordinarily complex and dehumanizing society which, unlike the societies of more stable eras, tends to *deepen* the individual's feelings of inadequacy and helplessness—his inability to cope with stress and to make decisions.

Because the neurotic patient's self-image may be poor, he takes great pains to conceal his presumed inadequacies from others, and their evaluations of his behavior can assume enormous importance. Furthermore, any real, or imagined, disapproval from others tends to induce disproportionately high levels of immobilizing anxiety.

In such cases, the neurotic patient may find himself in a peculiar kind of trap: severe anxiety—with its handicapping effect on both performance and concentration—may reinforce his sense of inadequacy and thus help perpetuate his already ingrained, habitual low self-esteem.

Librium (chlordiazepoxide HCl) In Today's Psychiatric Practice

In many such cases—when the patient's anxiety is, in the therapist's opinion, severely distressing and disabling—Librium (chlordiazepoxide HCl) often becomes a highly useful adjunct to psychotherapy. A dependable, effective antianxiety agent, Librium generally helps keep the neurotic patient's anxiety at tolerable levels, until such medication is no longer required. In addition, the calming influence of Librium may help the patient remain significantly less tense and apprehensive *between* counseling sessions—and may thus help to restore effective performance. In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated. (See summary of prescribing information.)

Librium®
(chlordiazepoxide HCl) 10-mg, 25-mg capsules up to 100 mg daily in severe anxiety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

You've talked...
you've listened...
but here she is again.

Looks like chronic anxiety.* Looks like a case for

Stelazine®

brand of **trifluoperazine HCl 2 mg. tablets**

For mildly anxious patients, your reassurance and some friendly advice will often carry the patient through the anxious episode.

But for chronic neurotic anxiety—the patient for whom anxiety is a constant part of life—medication may be required.

'Stelazine' can provide incisive control of anxiety, let the patient function more normally, and make her more receptive to your counsel.

* 'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

* **Indications**

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

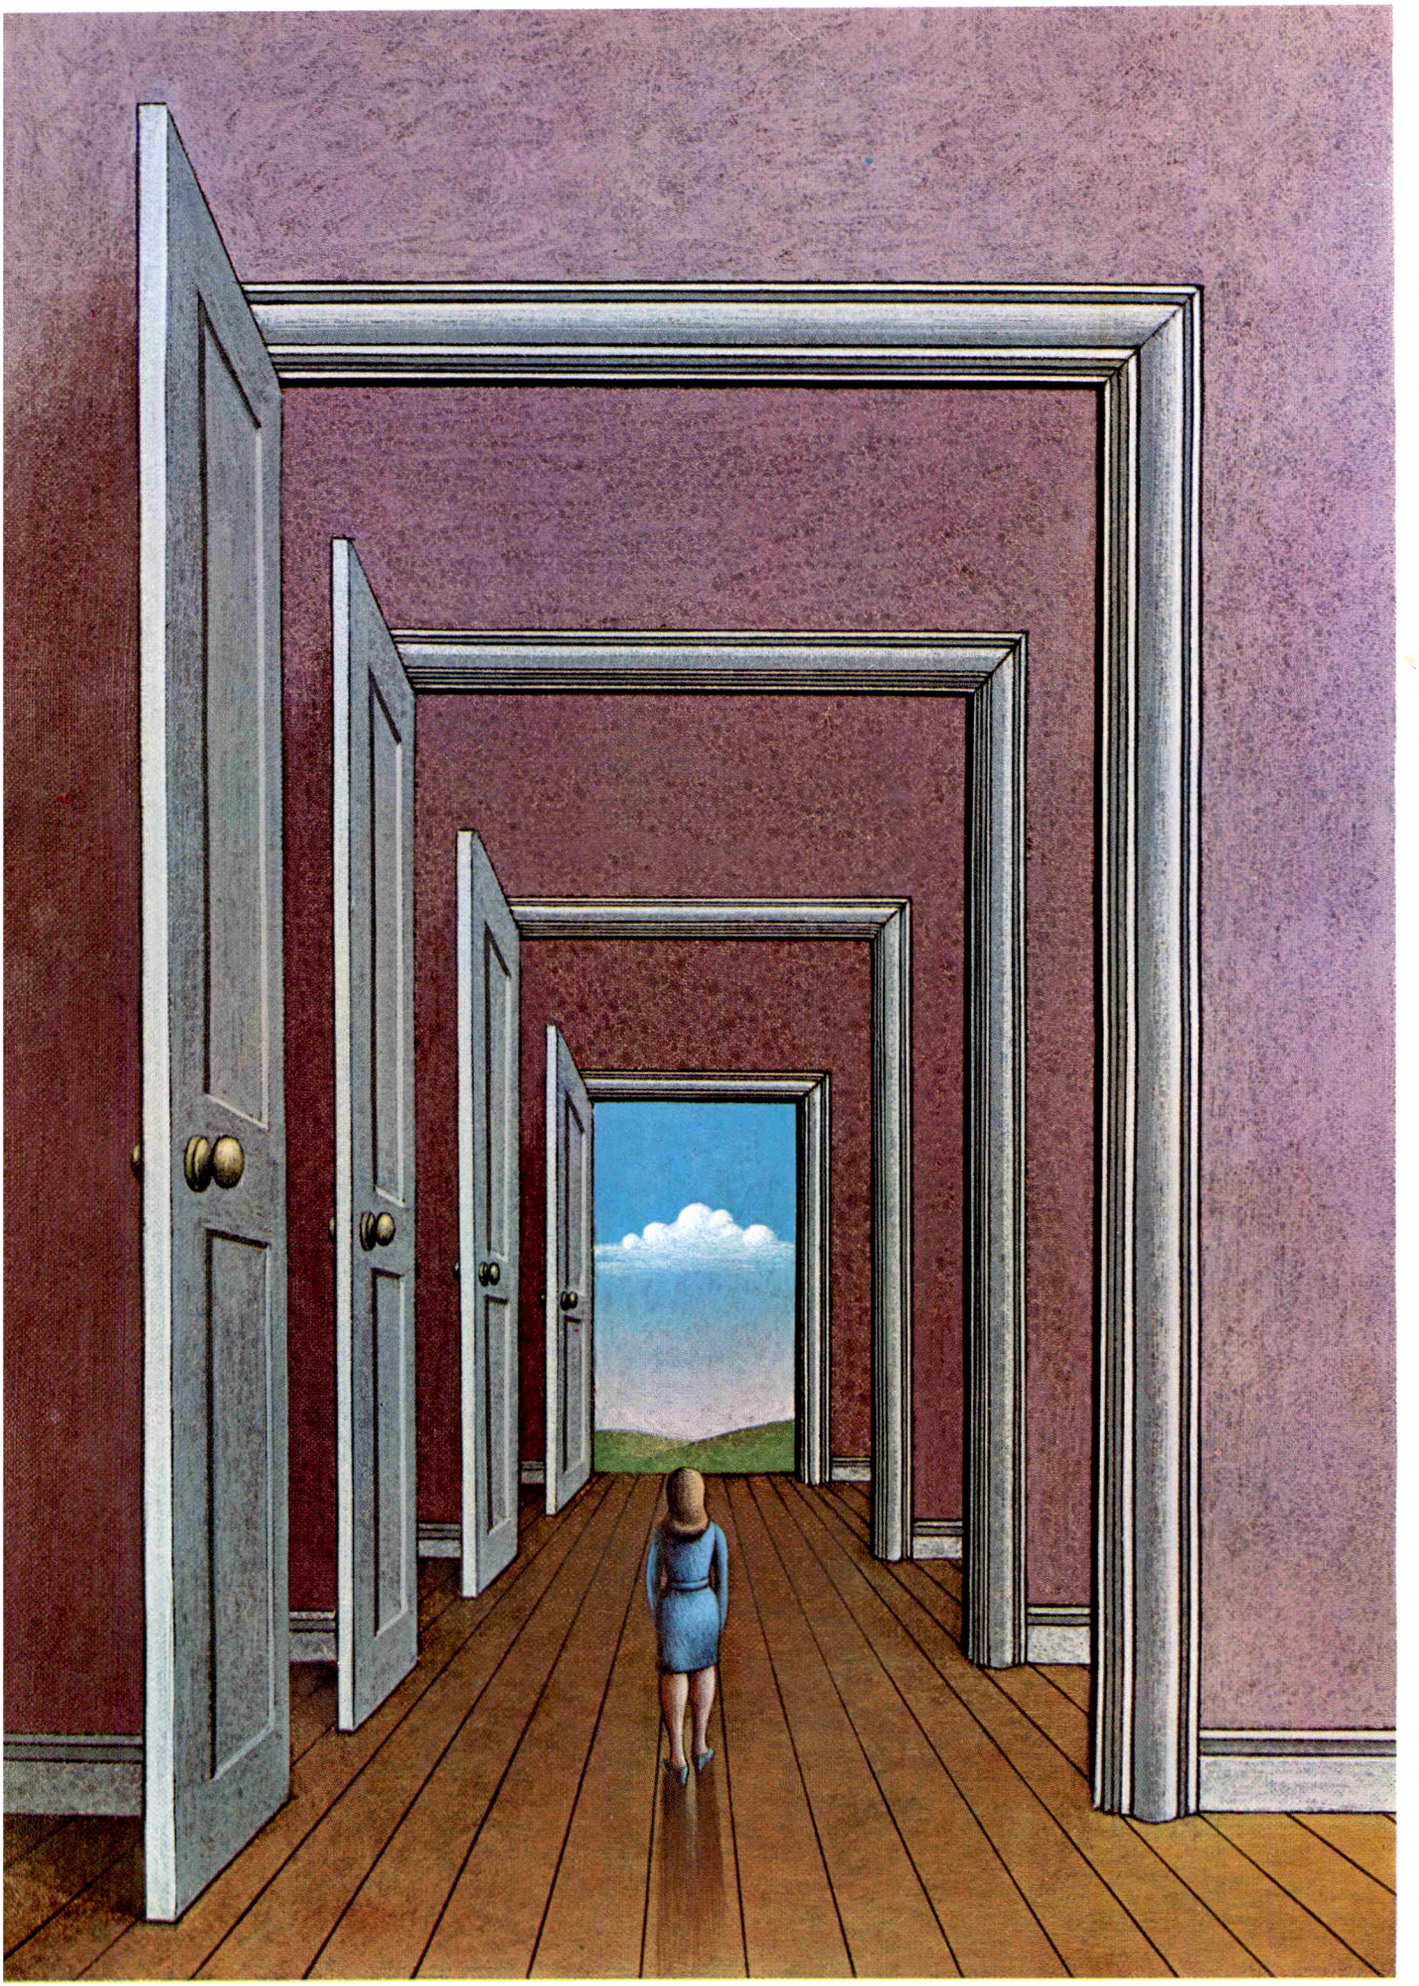
Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.



Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from Smith Kline & French Laboratories, Philadelphia, Pa

A24

A HEAD START FOR THE CLINICALLY DEPRESSED PATIENT.

All tricyclic antidepressants take from one to four weeks before optimal antidepressant effect is seen.

Sinequan (doxepin HCl)—the newest tricyclic antidepressant—is no exception.

But, in that waiting period, Sinequan alone offers the clinically depressed patient both:

prompt sedative activity to begin relieving the sleep disturbances often characteristic of depression, and

marked antianxiety activity to help relieve the apprehension, tension, worry and fear that usually accompany depression.

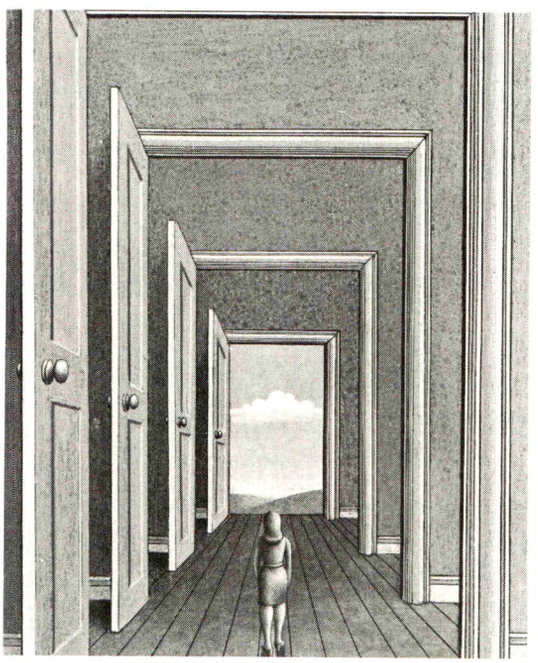
Further, the incidence of cardiovascular side effects with Sinequan is relatively low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) And Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses.

Prompt sedative activity. Marked antianxiety activity. Low incidence of cardiovascular side effects.

It's a head start for the clinically depressed patient.

THE NEWEST TRICYCLIC ANTIDEPRESSANT— WITH DIFFERENCES YOU CAN SEE.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules



Pfizer **LABORATORIES DIVISION**
PFIZER INC.

©1973, PFIZER INC.

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules

THE NEWEST TRICYCLIC ANTIDEPRESSANT–WITH DIFFERENCES YOU CAN SEE.

BRIEF SUMMARY

Sinequan® (doxepin HCl) **Capsules**

Contraindications. Sinequan (doxepin HCl) is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan (doxepin HCl) is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan (doxepin HCl) has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan (doxepin HCl) in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan (doxepin HCl). The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan (doxepin HCl) has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan (doxepin HCl), however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan (doxepin HCl) can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan (doxepin HCl) does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan (doxepin HCl) is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., and 50 mg. of doxepin in bottles of 100 and 1000.

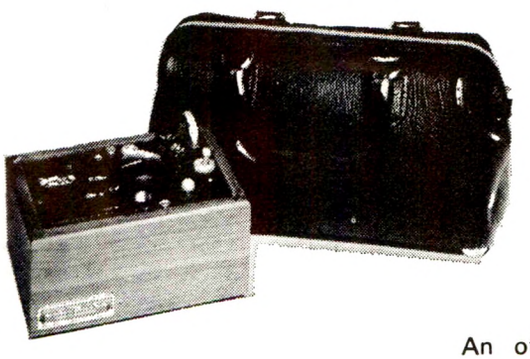
Pfizer **LABORATORIES DIVISION**
PFIZER INC.

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models– **PORTABLE FOR OFFICE AND CLINIC**



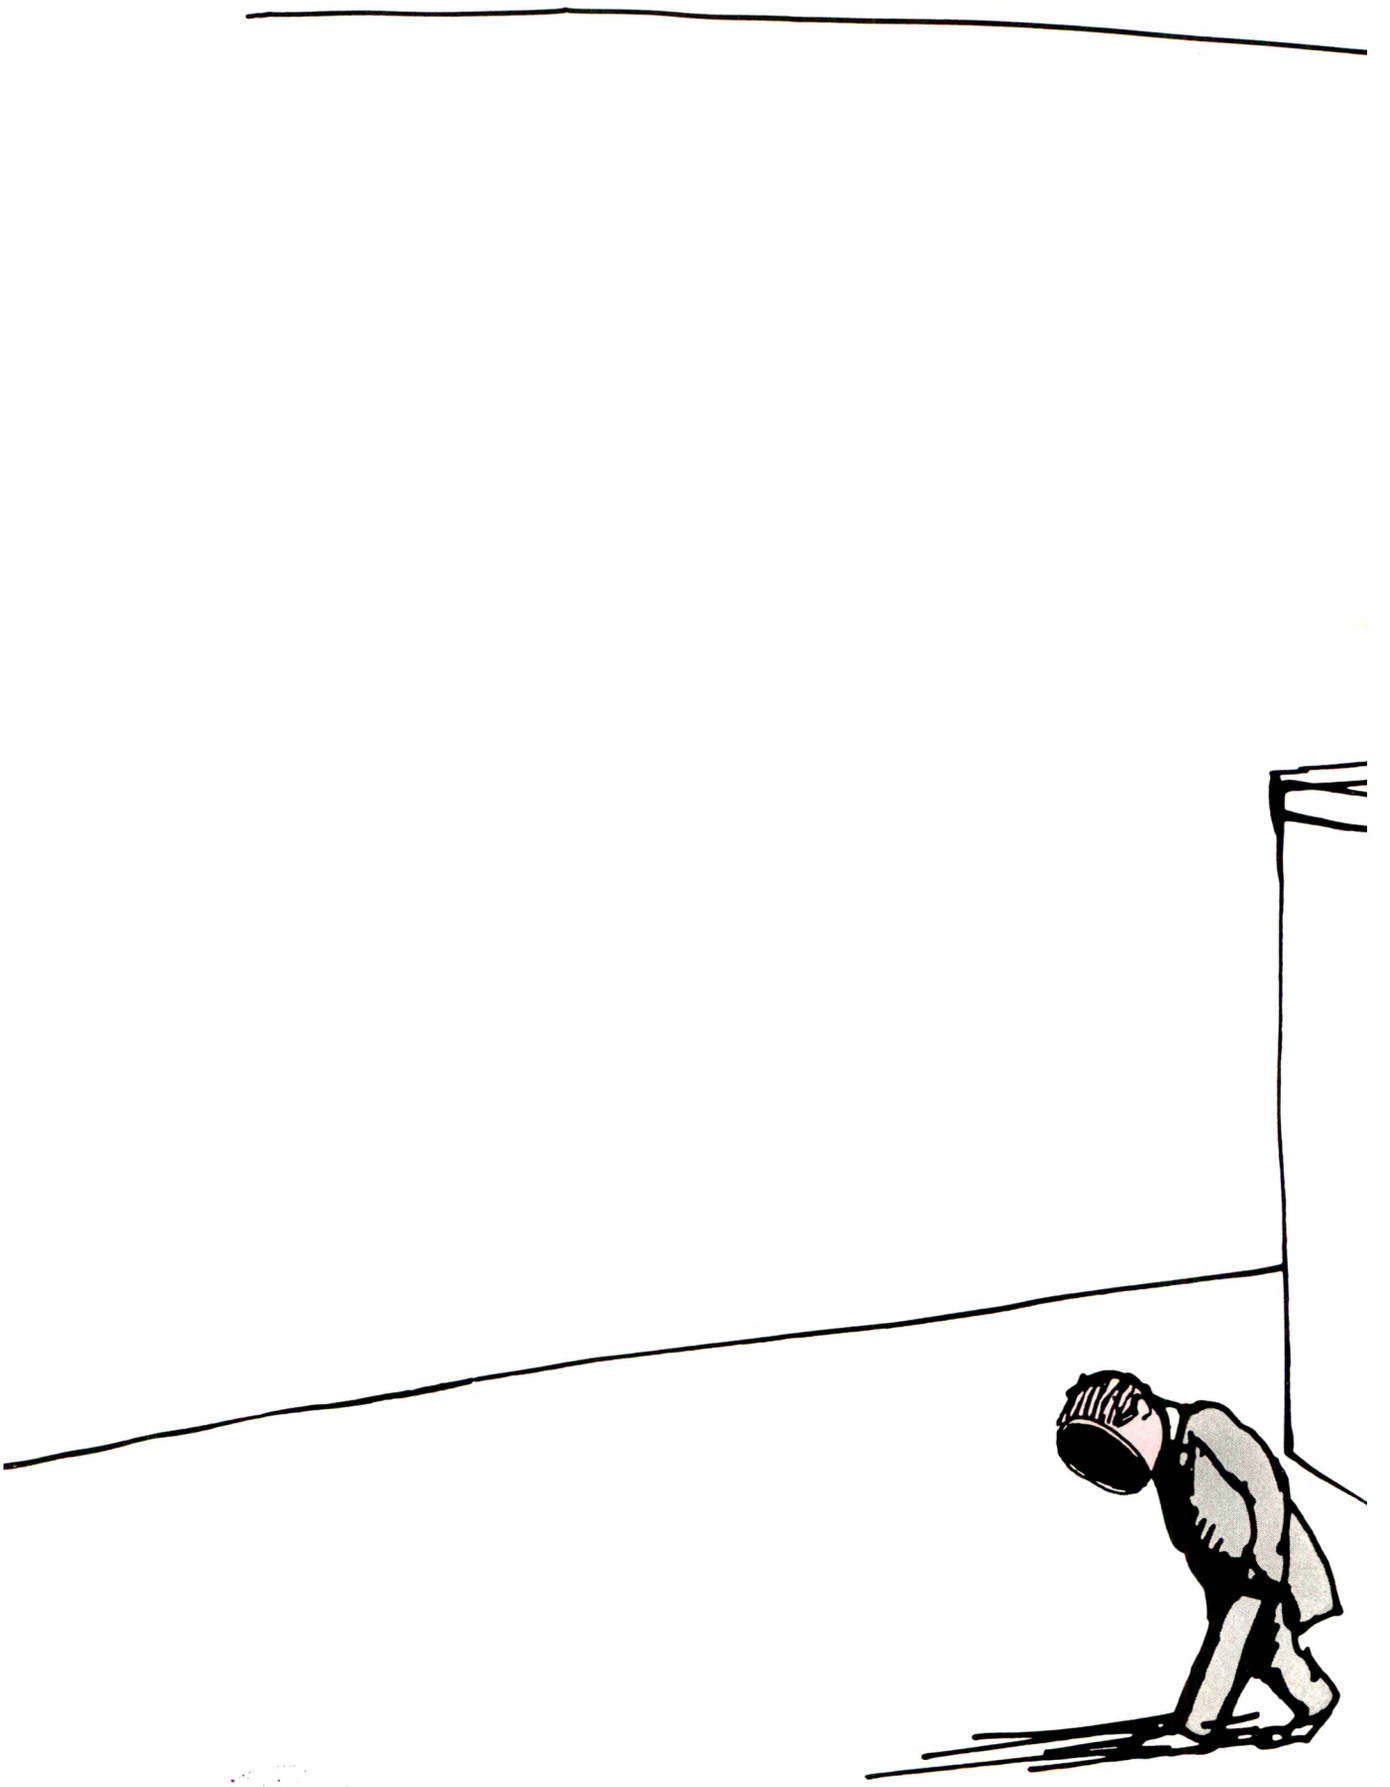
The Reiter MODEL SOS–THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives–patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

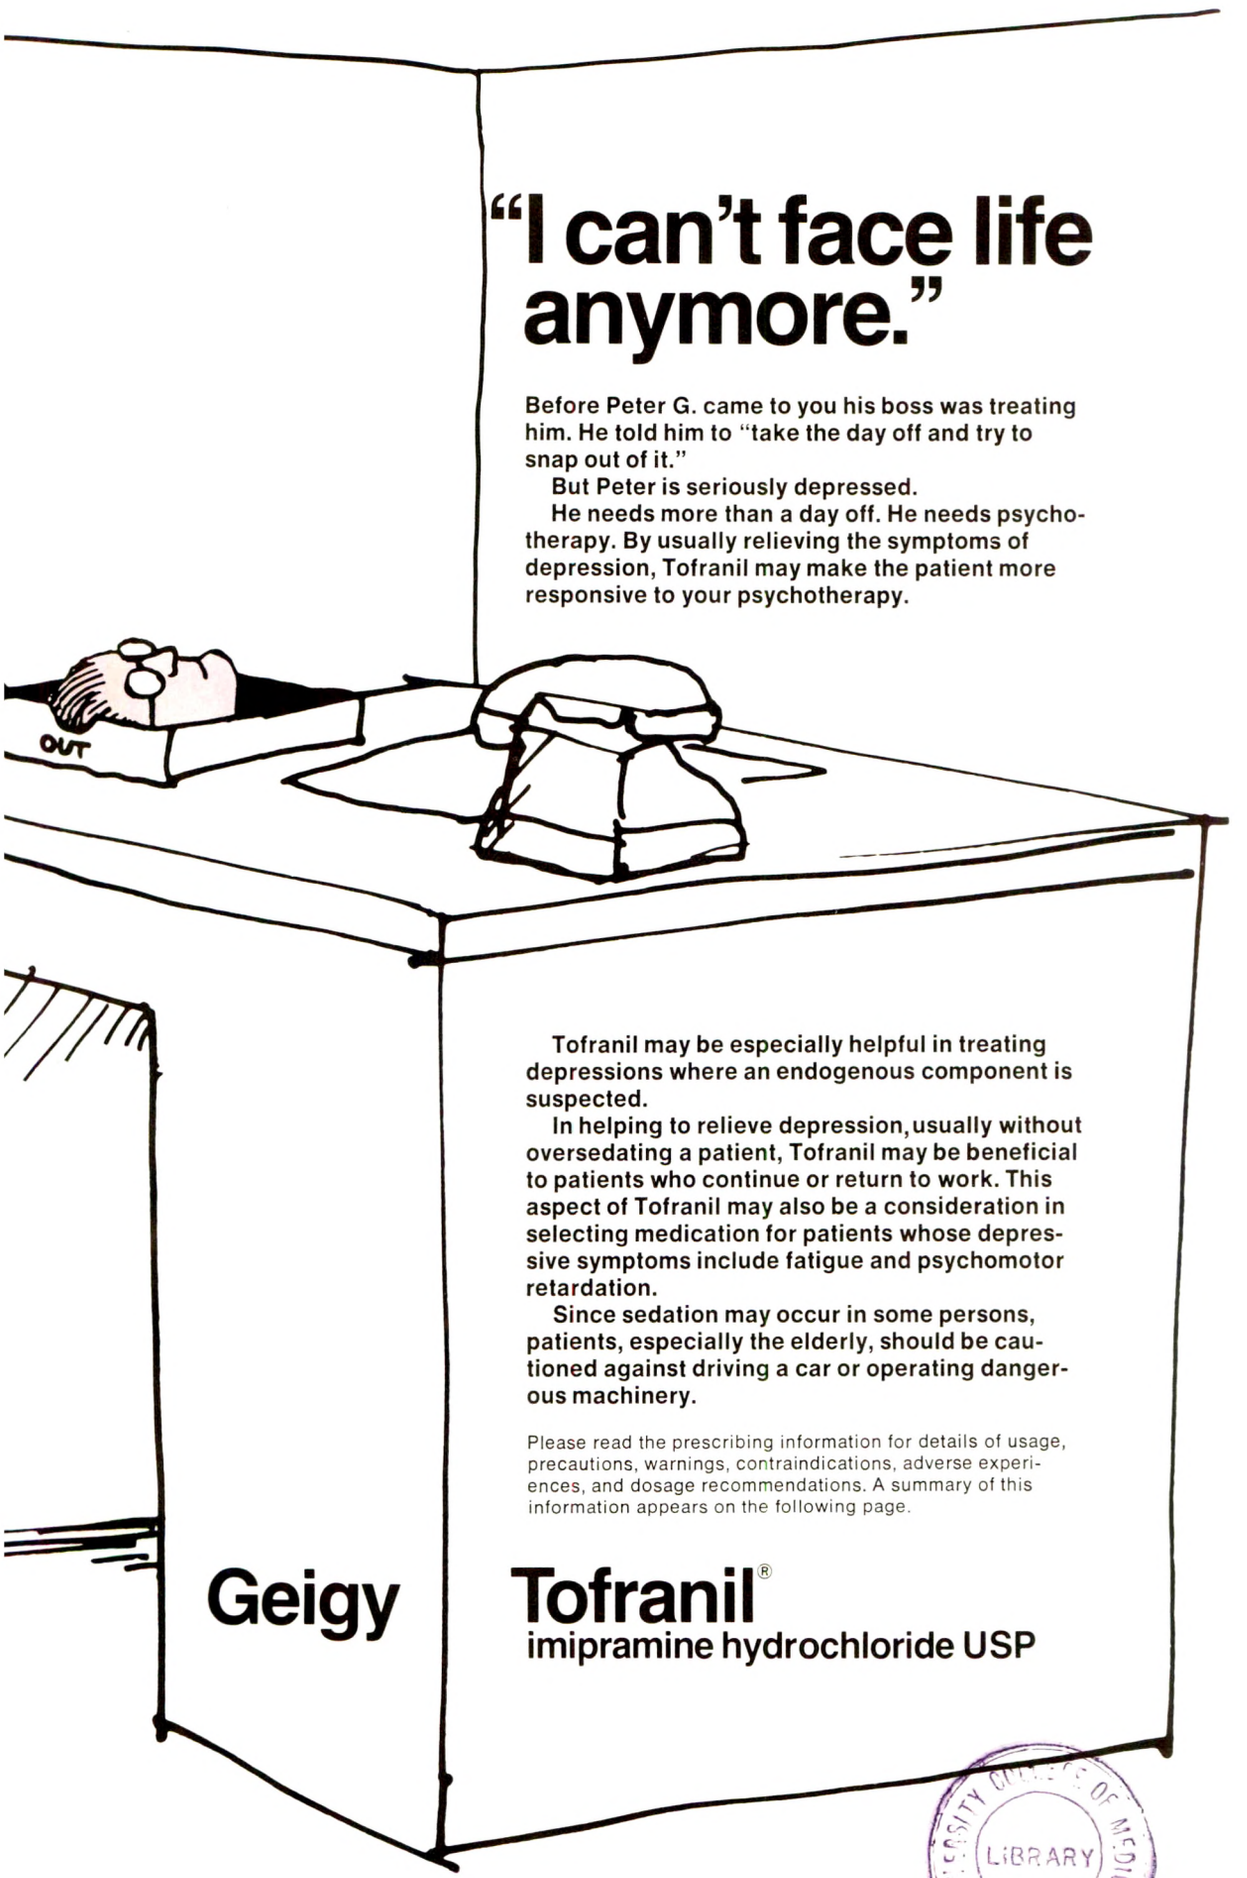
Available with this redesigned model, on request, the following special-purpose electrodes –a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.



The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.



An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

For more detailed information, and bibliography of over 200 references, write to:

REUBEN REITER, Sc.D., INC. 187 Sylvan Ave., Leonia, N.J. 07605 — Tel. (201) 944-1211

"I can't face life anymore."

Before Peter G. came to you his boss was treating him. He told him to "take the day off and try to snap out of it."

But Peter is seriously depressed.

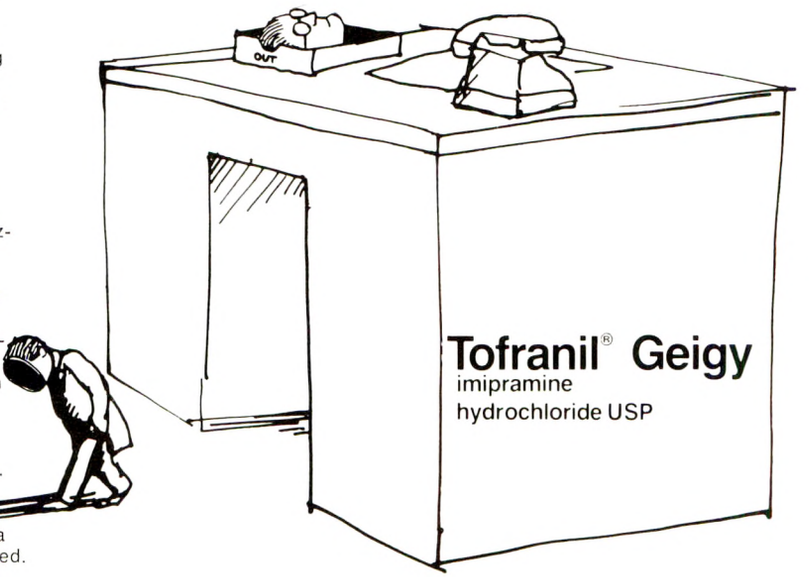
He needs more than a day off. He needs psychotherapy. By usually relieving the symptoms of depression, Tofranil may make the patient more responsive to your psychotherapy.

Tofranil may be especially helpful in treating depressions where an endogenous component is suspected.

In helping to relieve depression, usually without oversedating a patient, Tofranil may be beneficial to patients who continue or return to work. This aspect of Tofranil may also be a consideration in selecting medication for patients whose depressive symptoms include fatigue and psychomotor retardation.

Since sedation may occur in some persons, patients, especially the elderly, should be cautioned against driving a car or operating dangerous machinery.

Please read the prescribing information for details of usage, precautions, warnings, contraindications, adverse experiences, and dosage recommendations. A summary of this information appears on the following page.



Geigy

Tofranil®
imipramine hydrochloride USP

LIBRARY

Tofranil® imipramine hydrochloride USP

When depression comes to mind...

Contraindications: The concomitant use of this agent and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 14 days after M.A.O.I. therapy has been discontinued should be allowed before this drug may be substituted. Initial dosage should be low, increases should be gradual, and the patient's progress should be carefully observed. The drug is also contraindicated (a) during the acute recovery period after myocardial infarction, (b) in patients with known hypersensitivity to the drug. Cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

- patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
- patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
- hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
- patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
- patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Usage in Children: Pending evaluation of results from clinical trials in children, the drug is not recommended for use in patients under twelve years of age.

Since the drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as operating an automobile or machinery, the patient should be cautioned accordingly.

Precautions: Because of the possibility of suicide in seriously depressed patients, careful supervision during the early phase of treatment is necessary and hospitalization may be required. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, imipramine may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g. paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential.

Adverse Reactions: *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

How Supplied: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration. (B)98-146-850-J (7/7

"the work of one of America's psychiatric pioneers"

PSYCHIATRY AND ETHICS

by Maurice Levine, M.D.

introduction by Margaret Mead

biographical note by George L. Engel, M.D.

The late Maurice Levine, Professor and Chairman of the Department of Psychiatry at the University of Cincinnati, was one of the most eminent figures in the history of American psychiatry. *Psychiatry and Ethics* includes, in addition to the book-length title essay, a group of supportive papers and lectures, and a memorandum to his associates, written shortly before his death.

"Maurice Levine's style in psychiatry, in teaching and in therapy, and his last book all reveal his sense of the extra dimension given to understanding human behavior by the analytic practice itself." —*Margaret Mead*

"Dr. Levine was an inspired teacher of practising physicians and young medical graduates destined for careers in psychiatry. Whenever he lectured, he was always on the side of his audience. He was unique among his colleagues in emphasizing the alliance between the listener or the reader of whatever he had to say. His chapter on this subject is an original and fascinating contribution to our dynamic understanding of human relations.... This is a truly great book which will stand the test of time."

—*Leo H. Bartemeier, M.D.*

"Over the years and for many reasons, psychiatry and psychoanalysis have been misunderstood in many ways. Perhaps the most serious misunderstanding has concerned their relationship to ethical value systems and conduct. Dr. Levine's thoughtful and open-minded consideration of this challenge is uniquely clarifying and effective. It is this which makes the volume a unique monument to the memory of Maury Levine, and a great contribution to the influence of his life's work on our culture."

—*Lawrence S. Kubie, M.D.*

THE VITAL LINK

The community mental health center—vital link in the delivery of comprehensive psychiatric care

The community mental health center has emerged as a vital resource in community psychiatric services. Treatment at these centers is usually available to a large number of patients, yet therapy must meet individual needs.

Mellaril can help many patients with psychotic disorders who are being treated in the community mental health center. It is highly effective in reducing excitement, hypermotility, abnormal initiative, affective tension, and agitation—without causing euphoria, addiction, or undue sedation. (However, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, minimal extrapyramidal stimulation—notably pseudoparkinsonism—is a distinctive feature of Mellaril.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *CutaneousReactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

Social Systems and the Criteria of Health as Defined by the World Health Organization

BY ANDRZEJ JUS, M.D.

The main reason for the great discrepancy between the realization of the medical and the social criteria of health as defined by the WHO charter is the disproportion between the knowledge of technical sciences and of human nature. This is relevant to various social systems. There are in addition specific reasons for the discrepancies existing in Communist countries; such reasons include the practical difficulties inherent in creating a new human consciousness in a revolutionary way, a sharpening of the aggressive instincts by acceptance of the dogma of the class struggle, lack of an adequate communication system between the party and the population, and the instability of the value system, leading to a feeling of insecurity. Scientists of various disciplines represent the most productive social forces in society; they should play an important role in designing a unitary system of self-government for mankind.

AS THERE WILL BE SOME PESSIMISTIC REMARKS in what I am presenting here, let me at least start with an optimistic quotation from Julian Huxley (1): "The world has become a unit de facto: sooner rather than later it must become a unit de jure, by submitting itself to a unitary system of self-government."

However, Julian Huxley, as a scientist, was accustomed to think in terms of units of time measured by centuries; people of our profession are used to measuring time by the span of a human life or at the most a few generations. The progress of biological and technical science and the speed of political events is much more rapid than the evolution of the knowledge of human nature and the acceptance of humanistic ideals. Welch (2), summarizing a scientific symposium on aggressive behavior, wrote: "Those who are interested in making human social conditions more stable and wholesome will be particularly interested in the ability of environmental and situational factors to encourage the expression of aggressiveness in creative and beneficial ways. But our knowledge is yet only tentative and superficial. Our journey has only barely begun."

The achievements of contemporary experimental psychopharmacology, neurophysiology, and neurosurgery have important medical applications in psychic disorders, epilepsy, intractable pain, and involuntary movements. Such experiments, involving the stimulation or ablation of certain brain structures—for instance the amygdaloid and hypothalamic structures involved in aggressive behavior—contribute to our knowledge of brain mechanisms in various kinds of behavior.

However, the vision of controlling disturbed behavior by means of drugs or implanted electrodes suggests something not only horrifying but also extremely dangerous. This danger should not be overestimated because, as Kety has remarked (3), "Manipulation of the brain by any of the biological techniques which could be developed in the foreseeable future would involve such drastic invasions of the privacy, integrity and rights of the individual that, in their application, behavioral control would have been achieved even if the electrodes carried no current and the pills were placebos." I would go a little farther and say that even without common consensus for neurosurgical procedures, some purely external stimuli, especially those which Pavlov used to call "stimuli of the second signalling system," i.e., words, if applied in special social systems, could provoke in humans effects similar to those obtained in monkeys by Delgado (4), who used very sophisticated telemetric methods. The difference is that Delgado knew how to stimulate the pleasure center.

There are great risks in the lag in developing knowledge of human nature, compared with the exploration of the external world. Thus, knowledge of atomic physics is in the possession of human beings whose nature is far from adequately explored. The technical efficiency of

Dr. Jus was Chairman of the Department of Psychiatry, Academy of Medicine, Warsaw, Poland. He is now Professor of Psychiatry, Research Division, Laval University, Hôpital St. Michel-Archange, Quebec 5, Canada.

weapons has been better perfected than the ethical efficiency of human beings.

RELEVANCE TO PSYCHIATRY

Why are psychiatrists interested in such very general problems? There is certainly no statistically significant difference in the concern about politics of the psychiatrist as compared with other physicians or other professionals. Our concern is, however, qualitatively different because our profession is at the junction of the biological, behavioral, and social sciences. Even a layman knows that some psychic disturbances are caused by cerebral alterations and some by psychological or social factors that influence the central nervous system and act through the brain as intermediary, causing various behavioral disorders.

This does not mean that I fully agree with Wedge (5), who claims that psychiatrists, who are expert at treating disorders and conflicts within and between human individuals, should be actively involved in international conferences and negotiations so as to help in the management of relations among nations. I simply do not believe that politicians have so much respect for psychiatrists that they will readily take their advice. Like Brody (6), I think that clinical psychiatrists cannot at present offer anything better than (or even as good as) what behavioral scientists trained in psychology and social sciences offer. Besides this, I do not think that relations among nations can be improved over the long run without improving the nature of human beings. This may seem very complicated, but an oversimplification of these concepts, or an attempt to change human nature by governmental or intergovernmental decree, may bring tragic consequences. I will deal with this problem later.

Psychiatrists are not sociologists, even if they talk a great deal about sociology; the converse is also true. I am convinced that it would be a great error to analyze crucial social factors only from the point of view of psychopathology or psychodynamics. Even if the rules governing psychological and those governing social factors are somewhat similar, there is a qualitative difference resulting from the historical, political, cultural, geographic, and economic determinants of human behavior. As psychiatrists we may be successful, using adequate psychological and sociological methods of therapy, in reducing tension in families or in small social groups. We often know how to diminish discord among human beings and make them, if not happy, at least less unhappy. This is, however, only an experimental model in laboratory dimensions. It is at least as difficult to apply this kind of therapy to large social organisms as it is to apply the results of experiments on animals to human beings. However, laboratory discoveries form the basis for progress both in industry and medicine. I believe therefore that as psychiatrists we could add some important theoretical considerations to the problems of discord—and on higher or broader social levels than single family groups or groups working in a factory.

As equal partners, psychiatrists can contribute to a comprehensive understanding of international affairs (7). Perhaps we are better able than other professionals to determine psychopathological factors influencing social attitudes toward wars (8).

WHO DEFINITION OF HEALTH

The importance of social factors is expressed in some definitions adopted by the international organizations dealing with medical problems. At the beginning of its existence the World Health Organization (WHO) adopted a very general definition of health which assumed that health is partly a social concept. The relevant passage from the WHO charter is as follows: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease and infirmity." This is open to much criticism; I fully agree with Sir Aubrey Lewis (9) in his observation: "In describing health as a state of perfection, such as was enjoyed perhaps by archangels and by Adam before the Fall, the charter writers of the WHO were reverting to an ancient formula of unattainable wholeness of body, mind, and soul, realized in the Golden Age, but long since forfeited." Let me add only that the charter writers must have known very well that if we were to apply such criteria, it would be difficult if not impossible, mostly on the grounds of social criteria, to find a healthy person in the contemporary world.

The medical criteria of the WHO definition must be achieved by medical authorities who, of course, must rely on governments for adequate resources. Nowhere are these sufficient to the needs of the population. The reasons are different in different countries. In underdeveloped countries they include poverty, lack of money for the organization of health services, and lack of trained medical staff. In many wealthy capitalistic countries they include the lack of a system of nationwide medical care, the limitations of such a system in spite of advanced technological achievements, or simply poor organization. This is certainly tied up with the fact that national resources are allocated inadequately: more money goes to destructive than to humanistic activities. It is very important to make work in hospitals, outpatient departments, and research more attractive than one-to-one private treatment of a limited number of patients. This will open new perspectives in the reorganization of medical care in many Western countries, including the U.S.

In some Western countries (England, the Scandinavian countries), such organization is already very advanced and meets most of the needs. Many problems still remain unsolved because of practical difficulties.

PUBLIC MEDICAL CARE IN COMMUNIST COUNTRIES

In Communist countries the organization of public medical care is also very advanced. Routine services for

the entire population are based on principles of public health: free medical care, social welfare programs, and emphasis on fitness for work and on occupational and social adjustment. In the opinion of many Western psychiatrists, the public health model in the Communist countries has many advantages and is more advanced than in many Western countries (10–14). Kolb (10) emphasized the importance of outpatient departments in the Soviet organization of psychiatric care and wrote: "Other advantages of the Soviet system are: the guarantee of employment of patients on discharge; the provision that hospitals may pay families to care for the patient at home; the attachment of the psychiatrists to the dispensaries; the facility with which effective decisions and actions are made in regard to the economic, social, legal, and vocational life of the patient." To a certain extent these advantages are tied to the specific social system, but they do not seem to be incompatible with other social systems.

I will not discuss here whether good medicine is one of the positive elements of the Communist system or if, as suggested by Field (15), it results from the totalitarian concept that health, be it physical or mental, is an important strategic reserve. In my opinion we do not have sufficient data to analyze the complicated problem of the interference of human factors with a rational and at the same time cruel calculation, which might be true for any political system. I agree with another statement of Field, that objects seen from a distance look more undifferentiated and simple; only at closer range do they reveal their complexity (15). To put it in another way, I think that both theoretical humanitarian programs and practical (often cruel) reality affect government attitudes toward health problems.

Free medical treatment and such preventive measures as free education, the development of the vocational capacities of the young, and low unemployment are undoubted achievements of the Communist countries. Especially in psychiatry we can indicate a number of positive factors: extensive programs of outpatient treatment, intensive use of inpatient facilities, and free psychiatric care for everybody. But at the same time many factors inhibit the realization of all these principles. I will analyze here only those factors related to the social criteria of health.

Historical Factors

Let us not forget that many features of medical organization in the Soviet Union are the result of historical and cultural factors that are much older than the Communist system itself. Russian psychiatry in the nineteenth century was very humanitarian, and social attitudes toward mentally ill patients were very progressive. A strong trend toward community psychiatry already existed. There were small psychiatric wards as well as large mental hospitals. These factors have had an influence on contemporary Soviet psychiatry. On the other hand, in some other Communist countries it has been very difficult to change unfavorable public attitudes toward the mentally ill, to build community psychiatry, and to organize psychiatric wards in general hospitals. Once more we can see how important a retrospective study of cultural, sociological, economic, and other socially integrating or disintegrating factors is for an analysis of the development of psychiatry in a country (16–18).

Marxist Concepts

It is a pity that in this situation a dogmatic indoctrination may inhibit the progress of medical organization and research. Let me give some examples concerning psychiatry. According to the materialistic concept of Marx, there is nothing beyond matter. Probably because of that, great emphasis is laid on the organic etiology of many psychiatric disorders and there is some neglect of psychological factors such as interpersonal difficulties. This is especially true in child psychiatry. Somebody has forgotten (or was told to forget) that this contradicts another materialistic concept—that "social existence determines consciousness." This principle should be a strong stimulus for research on the influence of psychological and social factors on mental health.

Another example of such a contradiction concerns research in social psychiatry. The above-cited principle that "social existence determines consciousness" should stimulate research related to the influence of the new postrevolutionary social, economic, and cultural integration on the prevalence of psychiatric disorders. Such research is limited; it has been undertaken only in recent years and only in relation to some selected populations. In Poland, for instance, such research was started only ten years ago and has been limited to the influence of the migration of rural people to large industrial centers and the influence of industrialization on mental health. Somebody has forgotten (or was told to forget) about the differential influence of social factors on various social classes and especially the differing influences on the so-called "intelligentsia" and other social groups.

These examples show that although the purely medical criterion of health comes close to realization in Communist countries, there are some discrepancies that hamper the evolution of new trends in psychiatric treatment and research. Other questions concern whether the forms of organization of public medical care are adequate to the needs and the nature of the difficulties in realizing the basic principles of public health services. These important problems have to be discussed on a specific basis with specialists in medical organization.

DISCREPANCIES BETWEEN MEDICAL AND SOCIAL GOALS

However, the most interesting question involves the discrepancies between the realization of the purely medical and the social criteria of health. Such discrepancies exist in all systems that have adopted the principles of socialized medicine.

Of course in wealthy countries where no such system exists, a high percentage of the population is not only deprived of medical care but also of the feeling of social well-being. In underdeveloped countries, poverty limits

all possibility of such medical care. The wealthy countries that up to now have not developed an adequate system of public medical care will probably be forced to do so in the near future and to spend more money for health and social welfare. The underdeveloped countries still need help in this respect from international organizations.

However, the most intriguing question remains: Why are there discrepancies between the medical and social criteria of health in the Communist countries, which theoretically are based on the concept of the social well-being of the entire population? No other system promised so much in this field, and no other system has brought so many deceptions.

Maladaptation Not Always Pathological

Before discussing this problem in detail, let me make some comments on the expression "social well-being" in the WHO definition of health. Interpretations of these words may be varied and controversial. First, we must agree that without a good adaptation to the environment there is no possibility of social well-being. But social well-being, if conceived as the ability to adapt to a particular environmental or social structure, is not necessarily a criterion of health. The lack of adaptation to some social situations may even be an expression of personal courage and decency. If we do not take this into account we may be expressing uncritical approval of conformist attitudes. If, on the other hand, we do take this into account we must conclude that the failure to adapt to a certain social situation may have nothing to do with illness. There have been many examples where persons were labeled as suffering from personality disorders only because they did not adapt to the existing social situation; they had strong and ethically motivated reasons for their nonconformist attitudes. Thus, if we are discussing such problems from a medicosociological point of view, we must answer a crucial question: Is a person's lack of social well-being caused by illness in the medical meaning of the word, or is it caused by illness of the social environment, of a given social system, in the sociological meaning of the word? Of course an evaluation of the "illness" of a given social system will again be very controversial and will depend on social, political, philosophical, and cultural principles.

It is stating the obvious to observe that psychosocial elements play an important role in the etiology of some psychic disorders. However, it would be an oversimplification of mental health problems and of social problems to reduce the concept of psychic disorder to the problem of maladaptation. The ability to adapt adequately is only one of many mental health criteria. Very often an attitude that is evaluated by a given environment as social maladjustment is not necessarily an expression of psychic disturbance and loss of health. In this connection Sir Aubrey Lewis (9) wrote: "There are many forms of social deviations which are not illness, many forms of illness, which are not social deviation." The same author pointed out that "the criterion of health is adequate performance of functions, physiological and psychological. . . . Though our estimate of the efficiency with which functions work must take account of the social environment which supplies stimuli and satisfies needs, the criteria of health are not primarily social: it is misconceived to equate ill-health with social deviation or maladjustment."

If we completely divest the concept of mental health of ethical and political content, and express an opinion against the view of health as a social concept, we cannot agree that sociocultural disintegration is largely responsible for the high prevalence of psychic disorders among the lower socioeconomic classes in the Western countries. However, everyone agrees that there are causal links between social phenomena and psychiatric phenomena, even if one is very critical of the more prophetic than realistic WHO definition of health as a state of social well-being.

Thus we can say that some persons have problems of maladaptation because they are not healthy; social factors can be one of the reasons for their illness. Such persons need the kind of treatment that is often dependent on the solution of some very general social problems and thus may be beyond the limits of available psychiatric treatment. Other persons may have problems of maladaptation because the social structure is "ill"; they may consciously try to change, to "heal," this structure.

A detailed analysis of the impact of different social systems on the WHO's social criterion of health is beyond the scope of this article. But I do not want to restrict myself to making only general remarks—as, for instance, that totalitarian systems act in a deleterious way and liberal systems in a favorable way in regard to this criterion of well-being. Nor, as a psychiatrist, do I want to restrict myself to such general remarks as, for instance, that the possibility of free opposition, of expressing a nonconformist attitude, of being able to say no and to act in a nonconforming way, has the same value as the possibility of "abreaction." Of course individual abreaction without fear of repression, which is so common in totalitarian systems, would not change the history of mankind, but certainly it would make somewhat more bearable the lack of social well-being in a specific case.

REASONS FOR THE DISCREPANCIES

What are the principal reasons for the discrepancies in the Communist countries in which the purely medical criterion of health has been pursued from the outset with the greatest diligence and where public medical care is the basic health service principle? I will cite a number.

1. In my opinion one of the most important reasons is related to certain theoretical formulations of Marx and Lenin. I agree with Fromm's statement (19) that Marx "is supposed not to have been much concerned with individual man, his drives and his character, but only with the laws of society and its evolution." The classical statement of Marx that "it is not the consciousness of men that determines their existence, but on the contrary, it is their social existence that determines consciousness" is an excellent example of an oversimplified approach to the problems of human psychology. Without doubt, social

environmental factors are very important in the formation of personality and consciousness in a broad sense; some elements of this kind of approach also exist in modern currents of psychodynamic psychiatry. However, one should not neglect the important biological and genetic factors and the psychological factors acting on the human being since early childhood that have little or nothing to do with his social situation. Various drives are tremendously important in the formation of the human consciousness. On this oversimplified formulation have been based many popular misinterpretations by the epigones of Marx, such as that before the Communist era man was by nature driven primarily by the wish for economic gain. On the other hand Marx did not elaborate into a system some of his more sophisticated remarks (scattered in his different works) on alienation, on human nature, on the necessity to express human feelings toward the world and toward human beings, and they were not continued by his followers, who concentrated mainly on economic and political factors.

2. Another reason for the discrepancies is belief in the utopian idea that after the victory of the working class in the historical class struggle a perfect human being will emerge in the new society, which will have abolished the class structure. The impossibility of creating a new human consciousness under new economic conditions is one of the most tragic deceptions concerning Marx's concept of the relationship between social existence and human consciousness. To preserve the fruits of victory many sacrifices are demanded from the new society; they are sometimes inextricably bound with inhuman acts and a considerable restriction of human freedom. This again, as might be expected, has just the opposite result—the production of "superconformists," uncritical persons, or extremely nonconforming, hypercritical persons who either act in an open way and are subjected to repression or who dissimulate, which provokes a feeling of shame and unhappiness. Let us not forget that both extremes act in a state of complete lack of homeostasis and are subject to dramatic swings from one attitude to the other.

3. The introduction of a new social and economic system is fraught with many difficulties, including the abolition of the old and the introduction of the new. Even with the most sophisticated administrative measures this transition is not easy; often elements of the old have to be reconstructed (consider, for instance, the New Economic Policy of Lenin). However, it is much easier to change economic and social factors by revolution than to change the human personality, especially if the economic and social changes are executed at a high moral cost. The plasticity of the human psyche is qualitatively different from the plasticity of the social structure. Although it may be difficult to introduce new economic and social principles by revolution, it is much more difficult—if not impossible—to change the human personality and interpersonal relationships by revolution. The famous plasticity of the central nervous system described by Pavlov has limits dictated by general physiological laws and, in human beings, also by moral laws. This is another reason for the discrepancies between the social and medical concept of health in the Communist countries; a forced neglect of such laws produces a definite lack of social well-being.

4. Another reason for the discrepancies is the application of the principle of the class struggle to a new society. According to Marx the history of society is inexorably the history of the class struggle. I am not discussing here the principle of the class struggle as a stage in the history of the evolution of societies. This is a socioeconomic question, not a medical one. But even if we acknowledge the need for the class struggle we must remember that this is a struggle of classes of human beings, who should not lose their human characteristics. When the class struggle means the possibility of physical or psychic destruction of human beings, when intellectual arguments are changed into acts of violence, then not only social but also physical and mental well-being are in danger of dissolution.

5. Another closely related reason for the discrepancies is the creation of an atmosphere of lack of confidence. The slogan "Be watchful" has survived Stalin's period, when many decent people—labeled as enemies—were persecuted and killed. It is not easy to have a feeling of social well-being when one lives in a state of permanent watchfulness.

6. In my opinion one of the most serious reasons is the lack of adequate educational principles for the new generation. Ethologists have demonstrated the "plasticity of instincts." Instinctive behavior (defined by Lorenz [20] as an "innate behavior mechanism") may become maladaptive. If consciousness—as was claimed by Marx—is from the very beginning a social product, it is very easy to distort instincts instead of improving them. Without the knowledge of ethological principles it is easy to create maladaptive behavior. It is also easy, under special conditions, to override "species-protective mechanisms" and manipulate imprinting in order to convert the image of the human enemy (true or imagined) into that of another species. These remarks have been recently brought to the fore by some American psychiatrists. In relation to the work of Lorenz (20), they are investigating what can go wrong in the environmental interaction of infants and are trying to influence a variety of possibilities for adaptation. Man can deliberately alter the image of his enemy and believe that he is killing not a fellowman but a blood-sucking animal, a pig, a dog. The history of all wars is the history of this dehumanization of the human species. The principle of the class struggle contains the same danger of dehumanization of the class enemy.

7. One of the most important practical reasons is the lack (or the inadequacy) of communications within the Communist system. This fact has been recognized by the Communist regimes themselves as one of the greatest errors of unsuccessful party leaders. Unfortunately the error was labeled as such only after their death or political bankruptcy.

According to Ruesch (21), communication can be defined as the process that links discontinuous parts of the living world to one another. Communication is necessary at all levels of organization, from the single cell to com-

plex societies, and its disturbances are reflected on all levels. Through a good system of communication the human being tries to ensure a certain safety in his life—tries to realize the possibility of assuming what will or will not occur. The lack or inadequacy of communication between party leaders and the population in the Communist countries is caused by several factors. One of these concerns the principle of the dictatorship of the proletariat, which in practice is not dictatorship of the proletariat (i.e., of great population masses) but of the party's leaders. The other factor impairing the dialogue between the nation and the party's leaders is the lack of confidence and of sincerity. People are afraid to ask questions, which is incompatible with the dogma of Marxism, and leaders are afraid to tell the truth because the economic situation (aside from some indisputable successes) is not as good as it should be according to Marxist principles. If there is no sincere dialogue between the party and the population, if there is a lack of confidence and sincerity, then party decisions are based on false information, and credibility among the masses is lost. The feedback mechanisms indispensible to all communications systems are out of function. Decisions made without discussion with the population, and without prior notice, are accepted in silence to a certain point but with hidden tension. Beyond this point they are not accepted and are even, in desperation, rejected. This was the reason for the workers' riots in Poland in 1956 and 1970.

8. Another reason for the discrepancies concerns the instability of the system of values. This again is not peculiar to the Communist system; similar problems exist in other systems. Cantril (22), speaking of the human search for security in a physical and psychological sense, said that man, being a creature of hope, is not inclined to resign easily and that he wants to share a system of values and beliefs to which he can commit himself. The enthusiasm of the first commitment to the new system of values in a social system promising the realization of the noble ideals of freedom, equality, and brotherhood to all people, regardless of race and color, fades when the most worshiped values are denigrated. One of the most tragic and shameful examples of this was the wave of anti-Semitism inspired by one of the unsuccessful Polish leaders in 1967. In a country where six million people had been killed by the Nazis (among them three million murdered because of the racist ideology), the antiracist system of values, theoretically one of the principles of Marxism, was devalued in an official speech. The political leader of a Communist country had found a scapegoat on which he projected unacceptable and hostile impulses. Such a projective mechanism is common among totalitarian systems with their fanatical outlooks upon life.

NEED FOR INTERDISCIPLINARY EFFORTS

I have discussed in detail some reasons for the discrepancies between the realization of the medical and the social criteria of health in the Communist countries. This does not mean, of course, that there are no such discrepancies in other social systems. However, in democratic countries there is always the possibility of expressing criticism and no obligation to engage in dogmatic declarations. This is an important positive factor, not limited to the medical definition of health but bound up with general human rights. No normal person can fully enjoy medical health unless he has at least some freedom to express his own beliefs.

How then should we link all the aspects of the definition of health as expressed in the WHO charter? What must we do in order to be able to offer mankind "a state of complete physical, mental, and social well-being, and not merely the absence of disease and infirmity"? If we could accomplish this we would return to the Golden Age, relearn how to be true human beings, and end the destruction of our own species.

I refer again to Julian Huxley's statement (1) that the world "must become a unit de jure by submitting itself to a unitary system of self-government." But to achieve this—not in remote centuries but in a time measured by several human generations—we must concentrate all our efforts on a better exploration and knowledge of human nature. We must learn the mechanisms of species protection, how to use the "plasticity of instincts" for the benefit of mankind. This is our duty as scientists, and I believe that it is not utopian to expect scientists from many disciplines to collaborate in a future unitary system of self-government.

Interdisciplinary efforts by biologists, physicians, psychologists, sociologists, and pedagogues are needed to prepare a scientific program in order to diminish the discrepancy between the conceptual power of human thought and the weakness of social instincts. This is an agenda for many generations of scientists. Most if not all systems of education should be changed; we are already faced with such demands from the younger generation. It is not only a question of the program of studies but of their ethical framework. There should be much more study of mechanisms through which there can be proper channeling of aggressive and other destructive instincts, as well as study of negative reinforcement of such instincts starting in early childhood, the reduction of aggressiveness by genetic selection based on chromosomal investigations, the sublimation of instincts, the means of discharging some of them onto substitute objects, and the responsible channeling of the militant enthusiasm of youth. Principles of human relations between individuals and nations must be subject to imprinting from childhood. The new generations should never forget that the brutality of Nazism was directed toward creating a community of hate, of the annihilation of human values, and of anomie, which is a discord in the rhythm of social life (23). It was Hitler's belief that people do not grow through work and industry but only through hatred. Although the philosophy of other dictators may sound humanitarian, it is in reality quite antihumanitarian and cruel.

A united world is the only hope of contemporary mankind. If such a world is not realized, then we may be faced with another solution. A day will come when a man with

a club in hand will emerge from the cave to begin once more the history of a perhaps more happy humanity. This would mean that we are not the right edition of the species "homo" that is labeled "sapiens."

NEW SUBSCRIPTION RATES FOR THE JOURNAL

To keep pace with rising production costs, the Association has found it necessary to increase the price of subscriptions to *The American Journal of Psychiatry*. Starting with the January issue, the price was raised to: U.S., $15; Canada and South America, $15.75; other foreign, $18. A single copy now costs $1.75 plus postage.

Chronic Marijuana Use and Psychosocial Adaptation

BY JOEL SIMON HOCHMAN, M.D., AND NORMAN Q. BRILL, M.D.

The authors studied the life history and adaptation of marijuana users and nonusers in a randomly selected representative sample of ten percent of the UCLA undergraduate student body. Statistically significant differences were discovered in family and personal history; educational and work performance; legal history; marital and sexual adjustment; current adaptation; political, religious, and other values; and the use of other drugs. Chronic use of marijuana was not accompanied by significant deterioration in functioning or adaptation but was accompanied by increasing acculturation into a relativistic, gratification-oriented, stimulus-seeking value system.

MARIJUANA HAS BEEN TREATED as an illicit, dangerous substance since 1937. There have been numerous reports of pathological reactions to the use of the drug, though all have been anecdotal (1–5), drawn from foreign populations that are not comparable to American users (6–8), or highly selected (9). Reports of the increasing use of marijuana have been numerous (10) and it is now estimated that the rate of increase of use is 20 to 30 percent per year (11). No report to date has examined the effect of long-term, chronic use of marijuana in a user population that is representative of those principally involved in the burgeoning marijuana phenomenon.

In the fall of 1970 a longitudinal marijuana study project was initiated by a direct mailing to a representative sample of ten percent of the UCLA undergraduate student body, randomly selected by computer. The questionnaire, anonymous unless voluntarily self-identified, included 662 items and examined 14 specific areas of psychosocial adaptation, including personal history and demographic information, parents, siblings, educational history and adjustment, legal history, military experience, marital history and adjustment, sexual history and adjustment, work history, current living situation, politics, drug history, patterns of drug use, and effects of marijuana. In addition, approximately 100 subjects (every fourth self-identified student) were given a psychiatric interview.

The study focused on frequently voiced questions about alleged personality change (9, 12), lack of motivation (13), psychological morbidity (9), and social dysfunction.

METHOD

The questionnaire was mailed directly to the computer-selected respondents, along with a return envelope and self-addressed postcard. Only the postcard bore the respondent's name.

When the questionnaire was completed, the respondent mailed back both that and the postcard simultaneously but separately, enabling us to identify nonrespondents while keeping the questionnaires anonymous. We received a total of 1,400 questionnaires (64 percent of the total sample); 480 students voluntarily identified themselves for further study.

Every fourth volunteer was selected for further study, including a psychiatric interview. In addition half of the nonrespondents were contacted and their histories of drug use were obtained. All nonrespondents were matched with respondents according to characteristics determinable from school records (age, sex, race, major, college class). Both this information and the drug-use histories obtained from 400 of the nonrespondents matched the profile obtained from our respondents. Thus, whatever moved students to not cooperate was apparently unrelated to drug use, grade-point average, major, race, sex, or age.

We also checked the self-reported data against school records (such as grade-point average, number of changes of major, suspensions, etc.) and found the responses we received to be reliable. In combination, all these factors suggest a sound sample in which considerable confidence can be placed.

This study was supported by a grant from the Department of Mental Hygiene, State of California.

RESULTS

We will present summaries of only those findings which were statistically significant at the level of at least $p<.001$.

Incidence of Marijuana Use at UCLA

For our analysis, three categories of marijuana use were established: 1) no use of marijuana, experimentation only (defined as no use), or use less than ten times in the past year; 2) occasional marijuana use, defined as use from a mimimum of ten times in the past year to a maximum of twice a week for up to three years; and 3) chronic marijuana use, defined as use up to the present of three or more times a week for three or more years, or for two years if use approached daily frequency. Obviously these were very conservative classifications.

According to the above criteria, 65.5 percent were nonusers (47.8 percent had never used marijuana, 4.6 percent had only tried it, and 13.1 percent had used it in the past but had quit), 26 percent were occasional users, and 8.5 percent were chronic users.

Of the 52.2 percent of students who had tried marijuana at least once or were still using it, 40 percent had used it more than 50 times. Concerning current frequency of use, three percent used it daily, 14 percent used it several or more times a week, 29 percent used it several or more times a month, 32 percent used it less frequently, and 21 percent no longer used it.

The chronic users began smoking marijuana at a mean age of 16.5 years, while the corresponding figure for all marijuana users was 18. This suggests that there are personality and social factors which differentially motivate early initiation and continued use (14–16).

Seventy percent of the occasional users and 78 percent of the chronic users had been introduced to the drug by a close friend. Fourteen percent of the first group and 11 percent of the second had been introduced to it by acquaintances, and five percent of each by a sibling. Forty-one percent of the chronic users and 33 percent of the occasional users had been introduced to the drug in high school, as opposed to 13 percent of the experimenters. This supports the hypothesis that starting at an early age accompanies a pattern of heavier use.

The Use of Drugs Other Than Marijuana

We found that drug use among college students is extensive, that the use of all other drugs is associated with marijuana use, particularly if it is chronic, and that the use of all drugs other than marijuana is transitory in college students (see table 1).

There was no statistically significant relationship between marijuana use and the regular use of any other drug. It was concluded that marijuana use does not cause the use of other drugs but does accompany it. It appears that personalities that allow such experimentation fall along a gradient of increasing willingness for such experience—as individuals are more willing to more frequently experience marijuana intoxication, they are also more willing to try other drugs.

*Current use less frequent than several times a month.
**Current use several times a month or more.
***Consumption of more than five drinks in a three-hour period, once a month or more, excluding holidays.

In our sample, 78 percent of the nonusers said they intended to try marijuana in the future and only one percent of the nonusers said they believed marijuana use produced serious side effects. Since it is difficult to attend the university without knowing marijuana users, it may be that this lack of bad opinion of the drug reflects direct experience and observation.

Marijuana and Academic Performance

We found no statistically significant differences in the academic performance, in either high school or college, of users and nonusers of marijuana, even among the daily smokers.

Among the UCLA college students surveyed, frequency or duration of marijuana use, up to daily frequency, did not appear to affect the ability or desire to obtain high grades.

We found no differences between marijuana users and nonusers in the numbers of probations, suspensions, disciplinary actions, or expulsions. We did find that a higher percentage of chronic users than nonusers intended to go on to graduate school in a doctoral program (18 percent versus 11 percent). Several surveys have indicated that the incidence of marijuana use is much higher in graduate and professional schools, and one study reported that 85 percent of UCLA medical students have tried marijuana (13, 17).

There were no differences between marijuana users and nonusers with regard to: 1) number of changes in major, 2) number of changes in colleges, or 3) number of colleges attended. There was a significant difference between

chronic marijuana users and nonusers in regard to the number of interruptions in college study. Chronic users more frequently dropped out of school one or more times, but after their return they performed as well as their peers.

Our sample did not include anyone who dropped out and stayed out, and we are vigorously following all respondents in our original sample as they leave UCLA, for whatever reason, in order to resolve this shortcoming.

Forty percent of all students stated that they had a "significant amount" or "great deal" of difficulty in deciding their career goals.

Marijuana use varied considerably as a function of college major (see table 2). The largest incidence of marijuana use occurred among art majors (56 percent) and the smallest among prenursing students (nine percent).

Age, Sex, and Race

The incidence of frequent use of marijuana fell off strikingly in individuals older than 22, with peak usage in the group aged 19–20, reflecting the fact that widespread marijuana use is a relatively recent phenomenon. Studies of incidence in urban high schools indicate that marijuana use is continuing to increase; it is predicted that three years hence the incidence among 22-year-olds will be higher (11).

Women used marijuana less often than men; they constituted 35 percent of the chronic use group and 46 percent of the occasional use group.

Thirty-eight percent of all whites used marijuana. Spanish-American students used it with a comparable frequency, while 21 percent of blacks and 10 percent of Oriental students used marijuana.

Growing Up: Place and Religion

Twice as many individuals who grew up in suburban areas were chronic users as individuals who grew up in urban or rural areas (ten versus five percent). The location in which the individual had lived since age 18 was not significant, nor was the length of residence in the Los Angeles area.

Religion seemed to be related to marijuana use in several ways. Jews were overrepresented in the group of chronic users. Marijuana smokers more often did not follow the religion in which they were raised and more often became involved in nontraditional religions.

Of the Protestants and Catholics who smoked marijuana chronically, only one-sixteenth and one-third, respectively, continued their religious identification. Jews who smoked marijuana chronically did not give up their identification, probably reflecting the fact that being Jewish is more an ethnic than a religious identification today.

The frequency of religious practice was much lower among marijuana smokers: 20 percent of the nonsmokers attended a religious service once or more a week while only six percent of the marijuana smokers did.

Family Factors

Concerning the fathers of marijuana smokers, factors that had *no* significance were: father's citizenship, whether the father was alive, father's education and occupation, father's having the same religion as the respondent, father's use of tobacco, and father's use of all drugs except alcohol and illicit drugs. The father's use of alcohol and/or marijuana were both significantly correlated with the respondent's use of marijuana. The father's being an alcoholic was not significantly related to his child's drug use.

On the mother's side, factors that were significantly ($p<.001$) correlated with respondent's marijuana use were the mother's use of alcohol, tobacco, sleeping medications, pep pills, marijuana, or hashish. Similar findings have been reported in a survey done in Lincoln County, New York. The use of alcohol and tobacco by the mother cannot be simply interpreted as a causative factor, however, since 50 percent of the marijuana smokers had no such parental history.

Parents' divorce, the socioeconomic status of the family, and having stepparents were unrelated to marijuana use.

The size of the respondent's family was not significant, nor was reported sibling rivalry or discord. The smoking of tobacco by the oldest child was significantly related to marijuana use, as was the use of marijuana, hashish, barbiturates, amphetamines, and hallucinogens by older siblings. This and interview studies indicated that, if one child in a family uses marijuana, the other children are more likely to do so than are siblings of nonusers.

Although there was no relationship between reported family discord and marijuana use, and 50 percent of all students left home to go to school, 28 percent of the marijuana smokers listed wanting to get away from their parents and live on their own as the prime motivation for moving out, whereas only ten percent of the nonsmokers did so.

Marriage and Sexual Behavior

Both users and nonusers of marijuana were comparable in the incidence of marriage, divorce, and all data associated with marriage, including age at marriage; number of marriages, divorces, and separations; number of children; reported mutual marital and sexual adjustment; and number of extramarital sexual partners. Of those who were married, 90 percent of the chronic users and 96 percent of the nonusers and occasional users had had no extramarital sexual encounters.

Marijuana users began sexual experience at an earlier age, saw themselves as more experienced, had more sexual experience, suffered more venereal disease, and had a more liberal attitude toward sex than nonusers (see table 3). Marijuana users and nonusers did not differ significantly in regard to homosexuality, frequency of intercourse, or number of concurrent sexual partners.

No differences were found between the groups regarding the number of pregnancies, miscarriages, and illegitimate births. Roughly six percent of all women students had been pregnant at least once; two percent had been pregnant as many as three times. An interesting finding (significant at $p<.01$) was that, of those women reporting loss of time from work or school due to menstrual difficulties, 87 percent were nonusers of marijuana. Eleven percent of all women nonusers, compared with four percent of women marijuana users, had "symptoms" with their menses. It is of interest that tincture of cannabis was a classic remedy for menstrual cramps before the turn of the century.

TABLE 3

Sexual Experience and Behavior, in Percentages

Item	Nonusers	Occasional Users	Chronic Users
Am a virgin	52	20	6
Am sexually expert	30	58	65

Currently have only one sex partner	93	87	84
Total number of sex partners			
One	46	22	16
Five to nine	12	24	24
Ten to 19	7	14	15
Have had gonorrhea	2	5	9

Legal History

We found no differences between users and nonusers in the number of arrests for misdemeanors or felonies or in the number of convictions; 98 percent of the nonusers and 93 percent of the users had no such convictions.

There were significant differences between marijuana users and nonusers in two items of legal history: the number of moving traffic violations and a history of parole or probation. Seventy-three percent of those with no traffic violations were nonusers, compared with 21 percent of the occasional users and six percent of the chronic users. This finding may be related to the anti-authoritarian and thrill-seeking personality of the marijuana user that has been hypothesized. Although 65 percent of the chronic users reported occasionally or frequently driving while intoxicated, only eight percent reported receiving a traffic citation while "stoned."

Five percent of the marijuana users versus one percent of the nonusers had histories of parole or probation. Almost all of the marijuana users' probations were for possession of marijuana or another mind-altering drug. However, from our data it would appear that a marijuana user in the college population stands a one in 20 chance of being arrested for marijuana use over the course of three years or more.

Military Experience

Marijuana use was statistically unrelated to any variable connected with actual military experience among veterans. Only three percent of the occasional users were initiated into the use of marijuana while in the service. Apparently marijuana smokers who have sufficient intelligence and ambition to attend UCLA are able to perform as satisfactorily, without detection, as their nonsmoking peers in the armed forces (18).

There were considerable differences between users and nonusers concerning draft status and attitude toward possible induction (see table 4). Of those not having student deferments (2-S), 75 percent of those classified as conscientious objectors were marijuana users. All other classifications were equally distributed.

Work History

No differences were found regarding the age at which the first job was obtained, total number of full-time jobs, etc. Three times as many chronic users as nonusers (15 versus five percent) quit their jobs because they found them dull. Nonusers were twice as likely to stay on a job three years or more.

Current Life-Style

About one-third of the nonsmokers still lived at home with their parents, compared with 20 percent of the occasional users and ten percent of the chronic marijuana users. Six percent of the nonusers and occasional users lived in a fraternity house, compared with one percent of the chronic users. Chronic users rented a house eight times more often than did nonsmokers and eight percent reported living communally with two or more members of both sexes, an arrangement reported by no nonusers of marijuana. Eight percent of the chronic users, five percent of the occasional users, and one percent of the nonusers lived with a member of the opposite sex. Twenty-nine percent of the chronic users, 16 percent of the occasional users, and eight percent of the nonusers had lived in five or more dwellings in the past five years. In fact, 27 percent of the chronic users had lived in six to

TABLE 4

Other	22	33	24

*Significant at $p<.0001$.

ten dwellings during the past five years. Intercity mobility was similar: twice as many chronic users as nonusers had lived in four or five cities over the past five years.

There were no differences between the groups in total annual income, means of transportation, or total monthly expenses. Nonusers more often depended on their parents for income (47 percent versus 38 percent), spent more for food, and used more of their time for dating, sports, and television; all these differences were statistically significant. Thirty-one percent of the chronic users listed taking drugs with their friends as their principal use of leisure time, compared with three percent of the occasional users.

Significant differences in adaptation were revealed by the respondents' answers to the question, "Where do you go for help with a serious problem?" Twice as many nonusers as users turned to their parents first. Users were twice as likely to turn to a friend, male or female. The age of this friend was highly different for the nonusers, 20 percent of whom would first turn to an older friend, as compared with only two and four percent of the occasional and chronic users. Virtually no one listed a clergyman, teacher, sibling, or other relative as the first source of assistance. Surprisingly, nearly 17 percent of all the subjects reported that they would turn to no one. In summary, the nonusers appeared to have a more positive attitude toward age and authority, while users invested confidence in their peers. This may reflect the fact that few older persons have had experience with drugs or maintain an attitude compatible with the values of drug users.

Plans for the Future

Eighty percent of all students stated they intended to be in school next year, but 17 percent of the chronic users, compared with five and eight percent of the nonusers and occasional users, gave "unknown" or "undecided" for their plans for the next year. Two percent of the chronic users said they intended to drop out, whereas none from the other groups did. When the projection was extended to five years hence, 35 percent of the chronic users, 30 percent of the occasional users, and 17 percent of the nonusers were undecided. Projected to 15 years, 25 percent of the chronic users and 16 percent of the nonusers were uncertain about their future. Twelve percent of the nonusers projected themselves into high school teaching, compared with six percent of the chronic users; 18 percent of the chronic marijuana users planned to pursue college teaching, compared with eight percent of the nonusers.

It appears that chronic marijuana use is accompanied by less certainty regarding long-range plans and a self-acknowledgment of the possibility of change or evolution in interests. This is consonant with our impression that among chronic users there is a strong thrust toward involvement with the immediate rather than a delay of interest or activity for the future; nevertheless, their long-term aspirations are more ambitious.

Politics

Marijuana users are more liberal, more politically interested and/or active, more likely to have liberal parents, and more interested in altering the form of government and laws than are nonusers.

The percentage of all students who professed an interest in politics increased from 47 to 79 percent over the past two years. Twenty percent of the users were politically active two years ago, while only eight percent of the nonusers were. Currently only 12 percent of the users are still active, while eight percent of the nonusers still are. Total percentages of users and nonusers who described themselves as "extremely involved" fell as follows over the two years for which we have data: chronic users—from 12 percent to eight percent, occasional users—from two percent to one percent, and nonusers—from one percent to zero. This suggests that the reduction in activism was more related to what Keniston (19) called "student alienation" than to marijuana.

The percentages reporting they had liberal parents were: chronic users—33 percent, occasional users—26 percent, and nonusers—17 percent.

There were 573 students eligible to vote. Of these, 20 percent of the marijuana users and 14 percent of nonusers had voted in the last presidential election. The nonusers preferred Nixon to an extent twice that of the occasional users, and five times that of the chronic marijuana users (36 versus 16 versus seven percent). Thirty-five percent of the occasional users and 56 percent of the chronic users preferred "Peace and Freedom" or other third-party candidates.

Concerning changes students would like to see in society, in every instance of a "liberal" change, marijuana use was significantly and positively correlated with the strength with which the respondent favored the proposal. In fact, a graph expressing the relationship between marijuana use and liberality in politics is linear. This may be the result of the acculturation that accompanies continued use of marijuana and membership in the "drug culture," which is strongly liberal politically and antagonistic toward the present policy makers.

Driving

Alcohol: Four percent of the nonusers of marijuana

admitted to driving occasionally while drunk, as opposed to 15 and 19 percent of the occasional users and chronic users.

Marijuana: Twenty-seven percent of the occasional users never drove when intoxicated by marijuana. One-third of all users occasionally drove while "high," 32 percent of the chronic users frequently drove while "stoned," and ten percent said they always drove when "stoned."

Both marijuana users and nonusers were universally of the opinion that marijuana "intoxication" affected driving, but the users thought that they compensated by being more cautious, driving more slowly, and concentrating on their driving. Interestingly, the marijuana users enjoyed a good reputation for driving among nonusers. Only two percent of the nonusers thought marijuana users drove more recklessly while high. The users did report getting lost more frequently while high, which is probably due to interruptions in short-term memory. Eight percent of the occasional and chronic users had received a traffic ticket while "stoned." The fact that none of them had been discovered to be intoxicated, even while receiving the ticket, reflects the subtlety of the drug's effects.

Effects Experienced and Motivations for Use

Clearly, the most frequently experienced effects are euphoria, mellowness, decreased tension, and a feeling that time is passing slowly. The impression that tastes and sounds are intensified is reported only somewhat less frequently, and users report increased sexual pleasure and appetite, sleepiness, thirst, and a sense of increased creativity, awareness, and communication with others.

From our clinical work and interviews with chronic marijuana users we had derived the impression that a large portion of the effects of marijuana intoxication were so subtle that the subject required a period of initiation in order to learn to attend to the sensations that he otherwise would not perceive. Our data show that all the effects listed above are more often reported as the individual continues into chronic use. Beyond an explanation based upon the need to "learn" the effects, the possibility also exists that a neurobiochemical enzymatic activation may be necessary for the conversion of tetrahydrocannabinol to active cannabinols or their metabolites (20).

Regarding "hangover" effects, less than one-third of all users occasionally experienced sleepiness, mellowness, hunger, or tranquility the morning after intoxication.

Almost all users stated they principally used the drug while at home with friends as a social entertainment or before venturing out for outdoor or public events. Unlike the users of alcohol, marijuana users consciously and deliberately seek to alter their experience of the entertainment by being under the influence of the drug's effects.

Occasional and experimental users gave these reasons for use, in order of importance: 1) to feel good, 2) as something to do with friends, and 3) to relax. Approximately one-third of the chronic users stated that very important additional motivations were to increase their self-awareness, change their perspective, and increase sexual pleasure. Subjects reported that, with continued use, they learned to use the physiological effects of the drug to their own advantage. We have also amassed considerable evidence that experienced users are often able to "throw off" the effects of the drug when the situation demands it.

As the user becomes more acculturated into marijuana-using social groups, the drug and its immediate and long-term effects seem to become more important as a common social bond; 16 percent of the occasional users listed it as a very important thing to do with friends, while 47 percent of the chronic users did.

Attitudes About Marijuana with Continued Use

With continued use the user becomes more convinced that the drug is desirable and less convinced of its detrimental effects. This is strikingly different from the pattern one finds among alcoholics or opiate addicts. In these cases, the addict usually consciously perceives the addicting drug as increasingly undesirable, though it is increasingly desired unconsciously. This increasing desire expresses itself in increasing frequency of use and dosage. With marijuana use, frequency does not increase to the limits of physical tolerance; the individual seeks out his level of desired frequency of intoxication and stabilizes there.

Student Views on Marijuana Users

Subjectively, marijuana users described themselves as more sensitive, informed, rebellious, intelligent, idealistic, introspective, socially involved, sophisticated, well adjusted, conscientious, reliable, responsible, and cynical than nonusers. Nonusers agreed with them on sensitive, rebellious, idealistic, and introspective. Nonusers felt that users were less well-adjusted, ambitious, and religious, and more troubled. All students felt that users did not differ from nonusers significantly with regard to being well adjusted, antisocial, dirty, promiscuous, cynical, realistic, or studious.

DISCUSSION

The study presented here thus far casts considerable light on several questions. In a population of largely middle- to upper-middle-class American youth with above-average intelligence, achievement motivation, and opportunity in life, the frequency and duration of marijuana use had no correlation with academic achievement, which presumably reflects motivation. This aspect of our study has since been replicated by a study at the State University of New York at Stony Brook (21). These results challenge the validity of a commonly held theory that marijuana use results in an "amotivational syndrome."

There seem to be two major possibilities here: 1) that marijuana use may reduce achievement only marginally, so that middle-class persons who are experiencing persisting anxiety and "overmotivation" become less so through the use of marijuana, and then function effectively within the socially functional range of performance; and 2) that chronic marijuana use may accompany noneffective levels of performance, but in persons

with marginal motivation or psychosocial capabilities. In these persons, "amotivation" should be seen as far more intimately related to alienation (19), future shock (22), or other sources of psychologically and/or socially based dysfunction, rather than to drug use alone. Indeed, their heavy drug use may be most rationally seen as symptomatic of a dystonic emotional state. Experimentation or moderate drug use, in contrast, is best seen as comparable to similar patterns of use of alcohol. Our continued study is designed to investigate these hypotheses. Our findings to date clearly require that these questions be pursued.

The longitudinal study cannot answer questions about the impact of chronic marijuana use on those whose adaptation is too marginal or too low to achieve college-level study. But it clearly defines the impact of such drug use upon the mass of college users and narrows the question of amotivation to special populations.

It seems appropriate here to point out that, in the United States, the marijuana user is generally drawn from the most achievement-oriented classes, while in India and other countries having long traditions of cannabis use, users are generally from the lowest, least productive classes. For many reasons, these individuals are in no way comparable to marijuana users in America, and any generalizations from the experience of other societies to our own is a hazardous venture.

Except for the noted concordance between the use of consciousness-altering substances by parents and by their children, relationships between drug use and family background variables were not significant. We believe this reflects the fact that, increasingly, junior and senior high schools are becoming the main locus of acculturation into a peer culture that carries themes of drug use as well as other aspects of life-style and political philosophy. This explains the linear correlation between "leftness" of politics and marijuana use overall, even with many individual differences. Neither "causes" the other; we believe they are themes carried by the same vehicle—the youth culture.

It is our hypothesis that, as the polarization across age (40 seems the main dividing age) in our society increases, the peer group becomes so strong a socializing agent of values and life-style for youth that the effect of parental upbringing is increasingly being "washed out," at least in respect to drug use, political philosophy, and sexual behavior. The design of our longitudinal study will permit the gathering of extensive data on this question in the future.

In general, we have found no evidence that preexisting psychopathology, as such, is a significant determinant of marijuana use, including chronic use. We have a large sample of chronic users recruited from the general Los Angeles area, which includes many older users (our record holder has been "stoned" almost daily for 44 years), and the same is true of them. However, as noted earlier, marijuana users do appear to be more rebellious, reckless, questioning, anti-authoritarian, etc., than nonusers.

We have found no significant differences between marijuana users and nonusers in any area of psychosocial adaptation bearing on what may be reasonably considered the requirements of "good citizenship," with the exception of their views on the military and the draft, which are again views associated with the larger youth culture. The India Hemp Commission Report of 1894 (23) and each study since have exonerated marijuana of any connection with crime or acts of violence, and many studies have suggested that the relaxing and euphoric qualities of the drug render such acts less probable.

The current pervasiveness of the use of marijuana, along with the favorable attitudes toward it by both users and their nonusing peers and the consistent evidence of increasing incidence of use, down to and including the grade-school level, all predict that marijuana use will probably become a cultural norm within a few years for persons under 30. A good estimate of the ultimate percentage of users of any pattern is around 70 percent. A certain number of people will eschew marijuana for attitudinal, religious, or health reasons. The percentage of experimenters who have quit after finding the drug's effects not to their taste approaches 21 percent at UCLA.

Our study shows that, although other drug use accompanies marijuana use and was greater in both frequency and range in relation to the extent of marijuana use, this use represents experimentation, which becomes infrequent for the majority of drug users. At least for college students, acquiring an addiction to or regular use of a drug other than marijuana is so rare as to be remarkable, i.e., about 0.1 percent of marijuana users.

Finally, there is a point at which marijuana use reaches "abuse," in the sense that the person's ability to function is damaged. Probably about one percent of marijuana users reach this problematic level, representing an analogy to alcoholism. The dividing line appears to involve whether the individual stays intoxicated all the time. Persons who use marijuana daily, but primarily in the evening after the workday and on weekends (cocktail pattern), rarely show any loss of ambition or ability. But even when intoxication is constant, there are large individual differences. We have encountered many persons in creative and artistic occupations who manage to stay constantly "stoned" with impunity and maintain their productivity, and we have encountered more than several cases of computer programmers and other highly skilled persons who manage quite well while persistently intoxicated. One wonders, however, how much more they would accomplish without marijuana, and such people do seem to be an exceptional group, outside the general rule.

DISCUSSION

TERRY C. RODGERS, M.D. (New York, N.Y.)—Drs. Hochman and Brill have presented us with a well-designed statistical study of the life-style and current psychosocial adaptation of three categories of college students, namely, 1) nonusers of marijuana, 2) occasional marijuana users, and 3) chronic marijuana users. My remarks will be limited to a discussion of the chronic users.

The findings regarding the life-style, attitudes, and values of this group are in large measure consistent with the findings of other investigators (1). These include acculturation into the marijuana subculture with its antitraditionalism, unconventional mores regarding sexual behavior and work, political "liberalism," pacifism, and the active seeking of immediate gratification and altered states of consciousness through the use of psychedelic drugs. Though it is not emphasized by the authors, the data would also support the findings of both earlier (2, 3) and recent (1, 4) investigators as to the anti-aggressive effect of marijuana. However, findings regarding scholastic performance and self-assessment of personality traits are in rather sharp contrast to most of the recently published studies (4, 5).

The finding that even the chronic use of marijuana did not result in diminished scholastic performance or motivation requires special attention and some attempt at explanation, in view of the known toxic effects of heavy doses of cannabis. Though I have no ready explanation for this finding, a number of ideas come to mind.

This was a voluntary sample and therefore self-selective. It is conceivable that the more apathetic of the heavy users did not respond to the initial questionnaire. It is also possible that the socioeconomic and ethnic composition of the chronic users loaded this group with persons of superior intellectual endowment. Individuals from suburban backgrounds and Jews were said to be overrepresented in this group. In addition, grade comparisons were made across all fields of study without regard for the fact that certain disciplines are more intellectually exacting than others.

A more likely explanation is that the marijuana users among present-day college students are the distillate of an experience-screening process in regard to the capacity to use marijuana without serious disorganizing effects. Experimentation with marijuana among high school students has been commonplace for several years now. It is not unlikely that those persistent users who are especially vulnerable to its disorganizing effects never make it to college, or do not long survive if they do.

Another finding that suggests a self-screening process is the high incidence of subjectively pleasant effects of marijuana intoxication, together with a low incidence of subjectively unpleasant effects among the chronic users. The reverse characterizes the nonusers who have experimented with the drug. This is not to imply that we should take the self-reported claims of increased creativity, self-awareness, ability to communicate, and capacity for abstract thinking at face value. My own clinical experience suggests that the oft-claimed increased ability to communicate is invariably an illusory, purely subjective phenomenon and contrasts sharply with the perceptions of a nonintoxicated observer. More weighty evidence for this opinion is contained in Weil and Zinberg's (6) experimental study of the effects of marijuana on speech, which revealed marked impairment of narrative quality, coherence, unity, awareness of a listener, thought completion, and time orientation.

I have also been impressed by the consistent inability of those who claim increased self-awareness from marijuana use to describe these "insights" in language that I can comprehend. Invariably they resort to mystical, cosmic, and transcendental verbiage that makes the sociologist in Willie Morris' *North Toward Home* (7) sound like a paragon of clarity.

The marijuana users' egocentric view of themselves as more sensitive, informed, rebellious, intelligent, idealistic, sophisticated, and well adjusted than nonusers, together with their almost total submersion into the anti-authoritarian marijuana culture, raises some serious questions about the role of marijuana in locking these young adults into a prolonged, if not perpetual, adolescence. Our traditional concept of maturity and mental health is exemplified by Freud's dictum, "Where id was, there shall ego be." The marijuana culture stands this dictum on its head and, through the use of mind-altering drugs, actively seeks a state of "where ego was, there id shall be." It would seem that chronic marijuana users seek to be manipulators of their egos rather than strivers for ego mastery. In this sense, their psychodynamic structure is closer to that of the perversions than to that of the neuroses, and this may account for the absence of identifiable psychiatric symptoms in the present sample.

Questions of the Month

Each of the incomplete statements below is followed by five suggested completions. Select the one that is BEST in each case.

Question 1

Extensive studies of the extremely intelligent child show that such children are, compared to the average,

(A) less stable emotionally.
(B) more neurotic.
(C) more stable emotionally.
(D) physically weaker.
(E) more often the youngest siblings.

Question 2

The most striking and consistent abnormality in the sleep of depressed patients is

(A) prolongation of Rapid Eye Movement sleep.
(B) absence of Rapid Eye Movement sleep.
(C) high arousal threshold.
(D) diminution of stage 4 sleep.
(E) diminution of stage 2 sleep.

(The Questions of the Month are from the Self-Assessment Program of APA. The answers are supplied on page 164 of this issue.)

Reversal of Antiparkinsonian Drug Toxicity by Physostigmine: A Controlled Study

BY M. KHALED EL-YOUSEF, M.D., DAVID S. JANOWSKY, M.D., JOHN M. DAVIS, M.D., AND H. JOSEPH SEKERKE, PH.D.

Three female schizophrenic patients receiving a combination of psychotropic agents, including the antiparkinsonian agent benztropine mesylate, developed the central anticholinergic syndrome, consisting of hallucinations, anxiety, short-term memory loss, disorientation, and agitation. These symptoms responded dramatically to physostigmine salicylate administered intramuscularly; they were unaffected by placebo injection given on a double-blind basis. In patients receiving multiple psychotropic drugs, evaluation of whether the patient is acting confused because of the combined central anticholinergic properties of these drugs is important. When identified, this syndrome can usually be treated by reduction of the dose of the anticholinergic agents or in special instances by the use of the cholinomimetic agent physostigmine.

A NUMBER OF REPORTS have indicated that toxic confusional states may occur following the administration of such psychotropic drugs as phenothiazines (1–3), tricyclic antidepressants (4), and anticholinergic antiparkinsonian drugs (5–7), given alone or in combination (4, 6). Generally, these confusional states respond to dosage reduction or medicine discontinuation and are associated with signs of peripheral anticholinergic activity. The hypothesis investigated in this paper is that the confusional state seen with these drugs is essentially an atropine psychosis.

A number of reports have indicated that anticholinergic drugs, including atropine (8–10), scopolamine (11), and the various atropine-like antiparkinsonian agents (6), can cause a toxic confusional state (central anticholinergic syndrome) characterized by disorientation, lack of attention, agitation, visual and auditory hallucinations, anxiety, insomnia, illusions, loss of short-term memory, purposeless movements, pantomime activity with nonexistent objects, and agitation characteristic of an organic brain syndrome. This confusional state is also associated with anticholinergic toxic symptoms consisting of mydriasis, cycloplegia, temperature elevation, constipation, motor incoordination, dry mouth, flushing, and tachycardia and is dose related (11).

The physiologic basis of this "central anticholinergic syndrome" (8) is the *competitive* inhibition by atropine-like compounds of the neurotransmitter acetylcholine at the central cholinergic muscarinic receptor sites (12). Physostigmine salicylate, a cholinergic substance that crosses the blood brain barrier, can effectively antagonize both the central and the peripheral anticholinergic effects of atropine, scopolamine, and the synthetic anticholinergic drugs (13–17), competitively inhibiting the acetylcholine-destroying enzyme acetylcholinesterase. This leads to excessive accumulation of acetylcholine at the receptor (12, pp. 442–454). Physostigmine has successfully reversed experimentally induced delirium in normal volunteers intoxicated by atropine and scopolamine. In the clinical situation it has been used to reverse atropine and scopolamine coma (15–17). Physostigmine also reverses the organic brain syndromes associated with anticholinergic poisoning incurred by drug abusers and by individuals making suicide attempts with either over-the-counter sleep preparations containing atropine-like compounds or with tricyclic antidepressants (13, 15, 18, 19).

The reversal by physostigmine of the occasional toxic confusional state observed after administration of antiparkinsonian drugs in combination with phenothiazines and/or tricyclic antidepressants has not been investigated, and its efficacy in reversing the central anticholinergic syndrome has not been clinically studied using double-blind techniques.

The current double-blind study was conducted to determine whether the worsening of psychosis that we observed in a number of patients, which occurred after the administration of a polypharmacy of psychotropic and antiparkinsonian agents, is an atropine-like psychosis superimposed on the underlying schizophrenic illness.

METHOD

Three schizophrenic female patients received pheno-

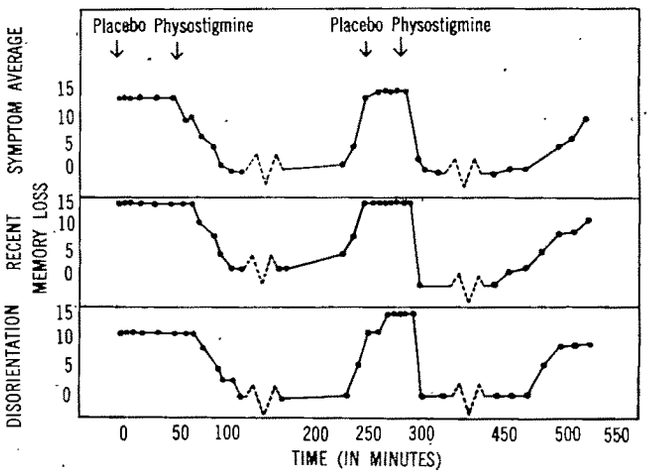
Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with Vanderbilt University School of Medicine, Nashville, Tenn. 37203, where Dr. El-Yousef is Assistant Professor of Psychiatry, Dr. Janowsky is Associate Professor of Psychiatry, Dr. Davis is Professor of Psychiatry, and Dr. Sekerke is Instructor of Pharmacology.

This work was supported in part by Public Health Service grants GM-15431 from the National Institute of General Medical Sciences and MH-11468 from the National Institute of Mental Health, and by research support from the Tennessee State Department of Mental Health.

The authors wish to acknowledge the assistance of Ms. Rochelle Dreyfuss in performing the laboratory experiments.

thiazine medication. Initially their psychotic symptoms were alleviated, but they developed parkinsonian side effects. Benztropine mesylate (Cogentin) was then added to the treatment regimen, and one patient also received a tricyclic antidepressant. The first patient received 150 mg. of thioridazine and 6 mg. of benztropine mesylate per day. The second patient received 150 mg. of imipramine, 72 mg. of perphenazine, and 12 mg. of benztropine mesylate per day. The third patient received 800 mg. of chlorpromazine and 8 mg. of benztropine mesylate per day.



Serial mental status examinations for the testing and rating of five target symptoms on a 15-point rating scale, with 15 being the most extreme, were used to rate: 1) visual and auditory hallucinations, 2) disorientation, 3) short-term memory loss, 4) anxiety, and 5) psychosis. Hallucinations were rated as to their severity and persistence. Disorientation was evaluated for the patient's comprehension of person, place, and time (day, date, and year). Short-term memory loss was rated as the patient's inability to remember three two-digit numbers given 30 seconds previously. Anxiety and psychosis were rated using a modified Bunney-Hamburg scale (20). Physostigmine and placebo injections were given during the confusional states. Each patient was given, intramuscularly, one or more doses of placebo and one or more doses of 4 mg. of physostigmine on a double-blind basis. Each was then evaluated for alleviation of the confusional state by raters who were unaware of whether a placebo or physostigmine was being administered.

RESULTS

Each patient developed a central anticholinergic syndrome characterized by a marked disturbance of short-term memory, impaired attention, disorientation, anxiety, visual and auditory hallucinations, and increased psychotic thinking. In all three patients these symptoms occurred in intermittent episodes, lasting from two to 12 hours. At the time of these psychotic-confusional states, there were peripheral anticholinergic signs in all three patients, consisting of dilation of pupils, constipation, dry mouth, and mild signs of dehydration. The patients were completely unable to remember three numbers after a 30-second delay, and they were unable to count backward from 20 to one. Their attention was markedly impaired and they were grossly disoriented. They episodically manifested vivid visual hallucinations to which they reacted. They had no idea where they were and could not remember the year, month, or day and, often, their names.

However, to the unsuspecting observer, the toxic nature of the symptoms was not obvious, since the patients were originally psychotic and confused because of their schizophrenic illness and the anticholinergic syndrome was superimposed over their "natural" psychosis. However, the clinical picture observed was actually specific when examined closely for target symptoms, since the short-term memory impairment was so striking and the pattern of visual hallucinations generally different from that of the preexisting schizophrenia. The most convincing proof that the patients suffered from the central anticholinergic syndrome was the dramatic reversal of the syndrome by physostigmine therapy.

FIGURE 1
The Effects of Placebo and Physostigmine in Reversing Benztropine Mesylate Toxicity in Patient H.G.

CASE REPORTS

Case 1. H.G., a 26-year-old married female schizophrenic, initially improved on thioridazine therapy and was given benztropine mesylate for marked extrapyramidal side effects, with poor results. The patient, who was interacting well and had no paranoid ideation, was receiving 150 mg. of thioridazine and 6 mg. of benztropine mesylate daily. Then, acutely and intermittently, she became anxious and had auditory hallucinations as well as a return of her paranoid thinking. She was delirious, unable to concentrate, had loss of immediate recall, and was disoriented in regard to person, place, and time.

She was given two placebo and three 4 mg. physostigmine injections, intramuscularly. There was dramatic clinical improvement after all three physostigmine injections, with reversal of all of the aforementioned symptoms and decrease in the rating scale values ten to 15 minutes after the physostigmine injection. This improvement lasted two to three hours. No change was noted with placebo. Figure 1 shows the effects of two placebo and two physostigmine injections in this patient. It is evident that neither the average score nor individual symptoms such as immediate memory and disorientation changed with placebo. Yet all scores were reversed within 15 minutes after the physostigmine injection, from severely impaired to close to normal, for about two hours. It is relevant to point out that physostigmine reverses experimentally induced scopolamine delusions for about this same time period (16).

Case 2. M.P., a 34-year-old chronic, withdrawn schizo-affective schizophrenic woman, was placed on 150 mg. of imipramine (Tofranil) and 72 mg. of perphenazine (Trilafon). She developed moderate extrapyramidal symptoms for which benztropine mesylate was given and gradually increased. When the dosage reached 12 mg. per day the patient exhibited anx-

iety, confusion, poor concentration, and disorientation in all three spheres and reported visual hallucinations of blood spots on her body, which she tried to wipe off. These symptoms were intermittent, lasting for one to three hours. Two placebo and three 4 mg. physostigmine injections were administered intramuscularly. The patient's toxic symptoms were alleviated within 15 to 30 minutes of the physostigmine injections; this improvement lasted one and one-half to two hours. There was essentially no change with placebo.

Case 3. C.W., a 14-year-old girl, was admitted in a withdrawn state; she had active auditory hallucinations and paranoid ideation. She was started on chlorpromazine, which was gradually increased to 800 mg. daily, and was given 8 mg. of benztropine mesylate daily for her extrapyramidal symptoms. In acute and intermittent episodes the patient exhibited a recurrence of her previously controlled auditory hallucinations and paranoid ideation and also exhibited concomitant delirious symptomatology with confusion, poor concentration, loss of recent memory, and disorientation in all three spheres.

She was given one placebo and two 4 mg. physostigmine injections, intramuscularly. No change was noted with placebo, but a marked alleviation of the aforementioned toxic delirium symptoms occurred ten to 30 minutes following the physostigmine injections. This improvement lasted more than two hours.

Table 1 presents the results of the central anticholinergic syndrome rating scale for the five variables studied, consisting of memory loss, disorientation, hallucinations, anxiety, and psychosis, and a full-scale score composed of the average of the individual items. The results represent an average ± standard error of the mean of the five placebo and eight physostigmine injections received by the patients. The table summarizes the ratings prior to placebo injection, 30 to 90 minutes after placebo injection, prior to physostigmine injection, 30 to 90 minutes after physostigmine injection, and 90 minutes to four hours after physostigmine injection. Placebo injection caused a very slight but statistically insignificant decrease in all five variables studied. In contrast, the physostigmine produced a dramatic decrease in the scores. These changes were clearly statistically significant and clinically dramatic. We also noted an increase in parkinsonian symptoms five to ten minutes after the physostigmine injection; these symptoms lasted ten to 20 minutes. With patient M.P., no change in the benztropine mesylate dosage was attempted and toxic symptoms stopped recurring after five days. In the other two patients, toxic symptoms disappeared within two days after discontinuing benztropine mesylate.

Multiple observations on a small number of subjects present a statistical problem without an elegant solution. Alternate analyses of these data utilizing either t tests between change scores (placebo-placebo base line versus physostigmine-physostigmine base line) or t tests between the mean for each subject in base line-placebo, or base line-physostigmine periods yield, as expected, essentially the same findings as the previously cited analyses. That is, there was no change with placebo and a statistically significant improvement with physostigmine on the individual dimension of immediate memory, disorientation, hallucinations, and psychosis, as well as on the average scores.

DISCUSSION

The previously cited information demonstrates that in our three cases, the toxic confusional state associated with the simultaneous administration of clinical doses of antiparkinsonian agents, phenothiazines, and tricyclic antidepressants for therapeutic reasons was alleviated by physostigmine injection, but not by placebo, administered on a double-blind basis. Thus the confusion was almost certainly due to anticholinergic toxicity. As contrasted to the confusional states occurring when parkinsonian patients are given anticholinergic agents for treatment of their primary disease, when preoperative patients receive too much scopolamine, or when patients intentionally take an overdose of anticholinergic agents, the central anticholinergic syndrome presents a difficult diagnostic problem in psychiatric patients. This is due to the fact that these patients may often already be psychotic, confused, and agitated, and the onset of the toxic confusional state may cause subtle, rather than dramatic, changes in mental status, which are in the direction of the primary psychosis. Indeed, Gershon felt that the anticholinergic drug N-ethyl-3-piperidyl cyclo-

TABLE 1

Improvement in Mental Status in Three Patients Receiving Benztropine Mesylate Following Administration of 4 Mg. of Physostigmine Intramuscularly

pentylphenylglycolate hydrochloride (Ditran) closely simulated or activated schizophrenic symptomatology in some patients (10).

It is our impression that the intensification of psychiatric symptoms in a psychotic patient treated with antipsychotic agents and antiparkinsonian drugs is a rather common phenomenon. Often such symptomatic deterioration is attributed to the patient being "allowed to regress" in the inpatient setting or to the patient's becoming worse due to the "natural course of his disease." The diagnosis of an agitated schizophrenic confusional state is made, and in many cases medications are increased, with a predictable subsequent worsening of symptoms. When the possibility of drug toxicity is recognized, the usual clinical practice is to stop all drugs, thereby causing the patient to be without the benefit of any antipsychotic agents. Consideration of the possibility of anticholinergic toxicity, careful mental status examinations, and thorough physical examinations focusing on the presence of peripheral anticholinergic signs may allow the correct diagnosis to be made and the selective, appropriate reduction or discontinuation of the medication to occur. In cases where the diagnosis remains uncertain or where the rapid alleviation of the anti-cholinergic symptoms is desirable, the use of physostigmine salicylate may prove a useful diagnostic and therapeutic tool.

However, the use of physostigmine salicylate involves the risk of excessive cholinergic-parasympathetic stimulation, especially for individuals in whom no anticholinergic activity is present. Such stimulation may present as tearing, salivation, rhinorrhea, sweating, pallor, miósis, hypotension, muscle weakness and fasciculations, bronchial constriction and dyspnea, nausea, vomiting, abdominal cramps, diarrhea, colic, biliary colic, urinary frequency, bradycardia, and asthma. Thus physostigmine should be used carefully or not at all in diseases in which cholinergic stimulation may be deleterious, such as ulcers, diabetes, hyperthyroidism, gangrene, ulcerative colitis, bowel obstruction and other gastrointestinal disorders, cardiac disease, respiratory disease such as bronchial asthma, bronchitis, and emphysema, bladder obstruction, glaucoma, pregnancy, myotonia congenita, and myotonia atrophica (12). The signs of cholinergic toxicity are often effectively alleviated by administration of up to 1 mg. of atropine sulfate given intramuscularly or intravenously (12, pp. 535–536).

We have found that an intramuscular injection of 4 mg. of physostigmine salicylate effectively reverses the anticholinergic toxicity in our subjects. Others have recommended from 1 to 4 mg. in the treatment of the central anticholinergic syndrome (13, 16, 17). Since, in cases of uncertain diagnosis, where 4 mg. of physostigmine may precipitate excessive parasympathomimetic stimulation due to lack of anticholinergic blockade, it is advisable to use physostigmine conservatively. We recommend the use of a 1 mg. intramuscular test dose of physostigmine followed 20 minutes later by an additional dose of 2 or 3 mg. Alternatively, physostigmine may be administered every 20 minutes in 1 mg. doses until symptoms are alleviated or until 4 mg. have been administered. Repeated injections are sometimes necessary if the physostigmine effects decrease before the anticholinergic effects have ceased.

It is important to note that, like others (15), we have found physostigmine salicylate difficult to acquire, since its noncentrally acting analogue, neostigmine, has superseded it in general clinical usefulness. From our survey we could find only one manufacturer in this country who produces injectible physostigmine (S.F. Durst and Co., Philadelphia, Pa.). Also, since it has no central activity, neostigmine is theoretically useless in treating the central anticholinergic syndrome.

We believe that it is likely that the anticholinergic effects of the antiparkinsonian agents, phenothiazines, and tricyclic antidepressants have an additive effect in precipitating the central anticholinergic syndrome. Indeed, phenothiazines have been shown to potentiate the effects of the anticholinergic coma produced by the anticholinergic agent N-ethyl-3-piperidyl cyclopentylphenylglycolate hydrochloride (21). Also, Davies and associates (4) have noted that 13 percent of all patients and 35 percent of those over age 40 treated with tricyclic antidepressants developed toxic confusional states. Significantly, 55 percent of these patients also were receiving perphenazine and benztropine plus a tricyclic antidepressant. In addition, the threshold for tricyclic toxicity in these patients appeared to be lowered, since five of 11 receiving a combination of drugs required less than 100 mg. of tricyclics per day to induce symptoms, while only one of nine receiving tricyclics alone developed the syndrome on less than 100 mg. per day.

Slovis and associates have shown that physostigmine can reverse tricyclic-induced central toxicity (19). Furthermore, Warnes (6), in reporting a series of nine patients with antiparkinsonian drug-induced confusional states, noted that one patient did not relapse when the antiparkinsonian agent was reinstituted and previously administered trimipramine was discontinued. All nine patients were also receiving either phenothiazines, tricyclic antidepressants, or both of these agents.

We have recently investigated whether chlorpromazine and/or imipramine can potentiate the anticholinergic effects of benztropine. In vitro experiments were performed on the longitudinal smooth muscle of the guinea pig ileum, using drug doses that produce approximately 15 percent reductions in a standard acetylcholine-induced contraction. Each drug added separately to the bath produced the following results: 5×10^{-9} molar benztropine = 16 ± two percent reduction; 5×10^{-7} molar chlorpromazine = 15 ± two percent reduction; and 4×10^{-7} molar imipramine = 14 ± two percent reduction. When all three drugs (at the doses previously cited) were added to the same bath, a 64 ± five percent contraction reduction was obtained. Since the percentage of reduction produced by the three drugs in combination is 19 percent greater than the additive inhibition of the same drugs acting alone, potentiation would appear to occur.

These data indicate that with our in vitro test, chlorpromazine and imipramine are approximately 1/100th as

effective as benztropine as anticholinergic agents. However, typical clinical daily doses of these drugs are as follows: benztropine, 4 mg., chlorpromazine, 800 mg., and imipramine, 150 mg. Thus relatively high milligram doses of chlorpromazine (800 mg./4 mg. benztropine) and imipramine (150 mg./4 mg. benztropine) in relation to benztropine are given clinically. If these amounts are converted to millimoles (mM) of drug administered, the amounts given would be: benztropine, 0.01 mM; chlorpromazine, 2.8 mM; and imipramine, 0.5 mM. Estimating in vivo relative potencies (moles of drug x potency, compared to benztropine) results in chlorpromazine being 2.8 and imipramine being 0.5 times as potent as benztropine in the doses used clinically. Furthermore, one would expect that the drugs would potentiate each other's anticholinergic effects.

We would caution against the uncritical extrapolation from in vitro work to central effects in man. However, we would like to point out that both chlorpromazine and imipramine at clinical doses produce anticholinergic side effects such as dry mouth, etc., in man. Thus in vitro findings are compatible with our hypothesis that the toxic confusional states in patients receiving combinations of these drugs may be the result of their combined anticholinergic effects.

Changing Styles in Psychiatric Syndromes: A Symposium

JOHN L. SCHIMEL, M.D., LEON SALZMAN, M.D., PAUL CHODOFF, M.D., ROY R. GRINKER, SR., M.D., AND OTTO A. WILL, JR., M.D.

A session of the annual meeting of the American Psychiatric Association in Dallas, Tex., on May 2, 1972 (a joint panel with the American Academy of Psychoanalysis), was devoted to "Changing Styles in Psychiatric Syndromes."

The participants were:

John L. Schimel, M.D., Associate Director, William Alanson White Psychoanalytic Institute, New York City, and Chairman of the Committee on Programs, American Academy of Psychoanalysis.

Leon Salzman, M.D., Deputy Director, Bronx State Hospital, and Clinical Professor of Psychiatry, Albert Einstein College of Medicine, New York City.

Paul Chodoff, M.D., Clinical Professor of Psychiatry, George Washington University Medical School, Washington, D.C.

Roy R. Grinker, Sr., M.D., Director, Institute for Psychosomatic Research and Training, Michael Reese Hospital and Medical Center, Chicago, and Professor of Psychiatry, Pritzker School of Medicine, University of Chicago.

Otto A. Will, Jr., M.D., Medical Director, Austen Riggs Center, Stockbridge, Mass.

Their papers are abstracted below.

Changing Styles in Psychiatric Syndromes: An Introduction

BY JOHN L. SCHIMEL, M.D.

TODAY'S SPEAKERS HAVE EACH SPENT 25 or more years in the practice of psychiatry. They are in a position to document the astonishing observation that the quality, intensity, and frequency—even the nature—of the syndromes of difficulty in living that come to the attention of the psychiatrist have changed during this period. It is not only the styles of the psychiatric syndromes that have been changing, however, but also the styles of the psychiatrists themselves. Although the changing psychiatrist is not the immediate focus of the papers, the members of this panel have been capable of changing with the times and have often been capable of anticipating and of pioneering significant changes.

My own psychiatric training experiences go back more than 25 years and include stints at St. Elizabeths Hospital in Washington, D.C., Bellevue Psychiatric Hospital in New York City, and various psychiatric installations in the Army during World War II, as well as psychoanalytic training. The most striking change during these 25 years is reflected in the current expectation that the psychiatric resident do something curative, or at least ameliorative, for his patients.

In my residency experience we functioned more or less like stock clerks in a department store: sorting, cataloging, and shipping patients to one or another warehouse. It was not very demanding work. It took my mind off my personal problems and I usually felt better after a day at the hospital. My work did not interfere with my propensity *not* to get involved with other people or to intervene in their affairs. I did not see any connection between my own discontents and the gravely disturbed patients with whom I was dealing, any more than I saw any connection between the state of my own robust health at the time and the tubercular or brain damaged. Being a psychiatric resident 25 years ago enabled me to enjoy what Erikson was later to term a psychosocial moratorium. I saw the humor but did not get the message offered by a patient at St. Elizabeths Hospital. This beautiful young black woman would dance before us as we made rounds, offering us scraps of paper and chanting: "Get your program here, get your program here, it is the only way you can tell the staff from the patients." At about the same time, or probably earlier, Harry Stack Sullivan was writing: "The patient is simply more human than otherwise." I got neither message.

My predicament arose from the fact that the psychiatrists I had met while in the Army who were psychoanalysts had impressed me and I had determined to become one of them. After some nine years of personal psychoanalysis my private life of reverie had been interrupted here and there; I could no longer so clearly see the differences between me and my patients.

The psychiatric resident of today, in some ways, skips the psychosocial moratorium the profession once offered and from the beginning is into the psychiatric bag of involvement and expectations of helping patients: in one-to-one patient encounters, in group therapy, and in crisis-oriented storefronts. He is bound to be a different kind of professional than his elder, although there are at present no data to indicate whether or not his professional role will be more socially constructive.

Changing Styles in Psychiatric Syndromes: Historical Overview

BY LEON SALZMAN, M.D.

WHAT DEFINES HEALTH OR ILLNESS, mental defect or mental health? The restrictions and limitations such labels can impose on an individual have consequences that go far beyond their immediate care and safety and involve prejudices and sanctions that can influence one's personal freedom. The degree of insecurity of the culture and its moral, ethical, aesthetic, and scientific standards enter into such definitions. Sociological, religious, and philosophical as well as decorous and conventional forms of behavior will also have a significant influence on diagnostic labels derived from scientific sources. In recent years, politics as well has entered into our nosological descriptions.

In 1848 Sir Arthur Morrison in his *Lectures on Insanity* in Great Britain said, "It is well known that the abuse of coition enervates the whole frame and in particular enfeebles the functions of the brain bringing on hypochondriasis, insanity and epilepsy. The baneful habit of onanism contracted in early youth frequently brings on imbecility of mind—sometimes mania and debility, moral as well as physical, so great as to incapacitate those who addict themselves to the solitary vice from any exertion either mental or bodily. The habit is particularly dangerous in old men, more especially if means are taken to produce excitement. I may here remark that an inordinate propensity for coition or onanism, together with an unusual desire for strong liquors, is sometimes the first sign of mental derangement" (1).

In a brilliant exploration of the Western orientation toward insanity, Michael Foucault (2) portrayed the changing attitudes toward madmen, who were considered part of everyday life and walked the streets in Shakespeare's plays and in Cervantes' *Don Quixote*. Only later were they considered public threats and dangerous to society. His study, extending from 1500 to 1800, suggested that mental illness is determined by complicated scientific, artistic, and religious phenomena, so that the view of the insane ranged from seeing them as tragic and unhappy individuals to seeing them as dangerous criminals requiring isolation and confinement.

WHAT CONSTITUTES MENTAL ILLNESS?

At the extremes our definitions can at times be precise and unequivocal. This is particularly true when we deal with those disorders which are physiological in origin and demonstrable in precise symptomatology. However, when we try to identify the subtleties of disorganization or maladaptation that arise out of our psychological capacities, we run into innumerable difficulties. In such instances we begin to deal with cultural definitions that are related to value systems and not to the basic physiological functioning of the organism. The differences between adaptive and maladaptive functioning will vary from culture to culture and will be more or less acceptable depending upon one's economic or social status.

Our conception of the etiology of altered functioning has a marked influence on the label applied to the phenomenon. The concept of disease as it advanced from a primitive magical basis to the ideas of a disturbance of bodily humors, germs, and finally a multicausal, highly sophisticated biochemical basis required a drastic revision of the prevailing classifications.

This is more notably the case in the psychological disorders, since nosology is intimately tied to the state of religious as well as scientific knowledge and to the existing sociocultural prejudices and preconceptions. Because we have no objective standards that can clearly identify or define mental health, we use a variety of determinants that grow out of our conceptions of mental health derived from moral and religious sources. When our knowledge of growth development is meager we are unable to distinguish between the normal physiological and the cultural requirements of behavior, and we tend to label any deviations from the cultural norm as disease processes. Behavior, rather than some underlying disease process, becomes the criterion. This is strikingly confirmed in our changing attitudes toward masturbation, which I referred to earlier. This fact can be documented over and over again. Because science develops in a cultural and historical context, it is contaminated with prescientific myths and superstitions. This unfortunately lends support to the periodic quasi-scientific attacks on psychiatric concepts which imply that mental illness is a myth or a political entity designed for exploitative purposes because it does not follow the medical model of illness or have laboratory tests to identify it. Instead of recognizing the validity of emotional disorders in a framework other than the historical medical-physiological pattern, these critics latch on to the deficiencies in our science due to its youth and inherent complexity and its present incapacity to identify the organic changes that may underlie many of our emotional disorders. With increased knowledge and greater sophistication we will be able to distinguish the disordered from the dissenter and the maladapted from the innovative, discontented individual.

Theoretical advances in the social sciences and psychiatry are generally slow and undramatic in contrast to the revolutionary and dramatic changes that occur when a new paradigm is introduced in the physical sciences. This makes the problem of revising our classification systems more difficult, since no definitive proof is forthcoming, nor can crucial tests be applied. The theory of relativity had a more profound influence upon the physical sciences than the cultural or social theories of personality development have had upon the social sciences. Yet they have both produced profound changes in the theoretical approach to the study of physics and psychiatry. Although there have been several revisions in psychiatric nomenclature in recent years, diagnostic categories still reflect outmoded philosophical or scientific attitudes. Thus it is not surprising to discover that the status of epilepsy as a spiritual disorder has only recently given way

to its recognition as a disease due to some abnormal focus in the brain. Only in the last 200 years have obsessional states not been considered to be states of possession in which either the devil or the Holy Spirit could overtake and reside in an individual and control his living.

CULTURE AND NOSOLOGY

In 1886 Krafft-Ebing described a case history in his *Psychopathia Sexualis* as follows: "According to the statement of his wife, the whole time of their married life covering a period of 28 years he was hypersexual, extremely libidinous, ever potent, in fact insatiable in his marital relations. During coitus he became quite bestial and wild, trembled all over with excitement and panted heavily. This nauseated the wife who was by nature rather frigid and rendered the discharge of her conjugal duty a heavy burden" (3).

Would we call this a disease today or the ideal of every woman? What would happen if we applied our present-day understanding to yesterday's categories of illness? In some instances we would need minor revisions, while in others we would need to make major theoretical and practical alterations even in such well-known categories as hysteria and schizophrenia. There is considerable agreement on the proposition that the cases described by Breuer and Freud in "Studies in Hysteria" would today be labeled schizophrenic.

Premature ejaculation is another condition that illustrates this thesis. When did premature ejaculation become an issue in men? It is clear that this syndrome did not exist prior to the emancipation and enlightenment of women. It is only since it has become possible for a woman to insist upon satisfaction from sexual activity that the problem has arisen. Although orgasm in the female did not occur frequently, this did not become an issue for the male until her pressure and insistence about her right to have pleasure too made it so. According to Krafft-Ebing, abnormally easy ejaculation is due to "excessive physical excitement or irritable weakness of the ejaculation center." Forel, in his book *The Sexual Question,* did not even mention this problem. I have had great difficulty in finding any article on this subject prior to 1900, and Dr. Ernest Jones said: "My impression is that hardly anything was written on that subject prior to Freud" (4).

Quite often a disease that has a variety of behavioral manifestations may be viewed differently in the same culture. For example, compulsive behavior is viewed quite differently when it involves an addiction to alcohol or drugs than when it involves the tendency to steal, as in kleptomania, or when it involves the tendency to overeat, as in obesity. Thus it is not so much the character trait or behavior that determines the consequences as the social, political, or religious attitudes toward the behavior. One may go to jail, be considered a saint or a sinner, or else be viewed as diseased and treated with care and concern.

Nowhere is this notion of cultural influence more marked than in our attitudes toward sex and maleness and femaleness, or in our attitudes toward qualities that characterize the Protestant ethic, such as industry and involvement, in contrast to the Eastern styles of detachment. Thus we come to grief over definitions of femininity and masculinity, and we use pejorative labels for certain aspects of behavior that indicate homosexual or latent homosexual tendencies, or activities designated as lazy, slothful, sinful, or the like. Here we must recognize that we are dealing not with medical or scientific statements but with cultural prejudices and preconceptions.

It is equally clear that our treatment modalities are also heavily involved not only with prevailing scientific conceptions but also with the culture. The value of work as a preventative and cure, which is related to the Protestant ethic, needs to be contrasted with the value of knowing oneself and achieving the sense of detachment that characterizes some of the Eastern philosophical systems. It has given rise to psychoanalysis, with its influence and acceptance in the West, even while it is being altered by existentialist and Eastern influences.

MEDICAL AND NONMEDICAL MODELS OF ILLNESS

The science of nosology, which was related to the healer or medical model, requires a drastic overhaul when the model gives way to a sociocultural or developmental model in which disordered living may or may not be an illness. Such psychological malfunctioning need not follow the medical model but instead could be considered a maladaptation that renders the individual less effective and less adaptive as a functioning animal. The shift from a medical to a nonmedical model of illness must also take into consideration the prevailing modes of healer-patient interaction. Three varieties can be noted:

1. The wise, magical healer relationship in which the healer is possessed of spiritual virtues and wisdom and is able to alter the behavior of individuals in striking ways. The patient is required to accept the authority, whether it be a physician, psychoanalyst, or priest, with faith and spiritual conviction.
2. The skilled, detached scientist who is uninvolved and ruthless, although somewhat less grandiose in that he recognizes his limitations and his responsibilities. He functions also as a specialist who attempts to directly influence disturbed functioning but uses techniques that do not depend entirely upon his charisma and magical qualities.
3. The expert partner relationship, in which the helper is a supportive individual who guides and encourages with his knowledge and understanding and enables the patient to grow through his own understanding.

These three models relate to the spiritual, charismatic, and authoritarian therapies based largely on faith, and those which attempt to educate the individual to mental health. The categories are related to our knowledge and understanding of disease processes and determine the character of health delivery systems. Consequently, our capacity to heal influences the disorders that require heal-

ing. As this occurs the prevalence of certain syndromes will become apparent while others will disappear. What is considered to be abnormal today may be considered healthy and reasonable tomorrow. This is true with our major disorders like the psychoses as well as with the widespread behavioral changes manifested in the neuroses. Therapy will ride hard on our changing concepts, as we have witnessed in the 40-year span that has included shock therapies, lobotomies, drugs, and a multitude of individual and group therapies.

Changing Styles in the Neuroses

BY PAUL CHODOFF, M.D.

THE TERM "NEUROSIS" was born in 1769 when William Cullen first used it to designate a general class of diseases due to "disordered motions or sensations of the nervous system" (5). Included were a mixed bag of neurological, psychiatric, and medical conditions; it is clear that Cullen meant something very different than we do today. However, his contribution was significant because he introduced not only a name that took root but also the idea of functional illnesses (6)—those due to deranged physiology but without pathologic alteration. In addition, by replacing the dominance of the body humors with that of the nervous system, Cullen made it possible for certain individuals to complain of suffering from "nervousness" rather than "the vapors," being "out of humor," or possessed of demons, as they might have done in previous epochs.

During the century after Cullen, what was meant by neurosis gradually approached its current state as scientific medicine expanded and the true cause of many diseases was understood, thus allowing a separation of functional or psychogenic conditions in which emotional or "moral" influences were determining factors from those definitely attributable to organic lesions. Conditions that today are included within the loose confederation of the neuroses share certain characteristics. First, they are nonorganic in their origin, although not necessarily in their consequences, and are considered to be the product of psychologic-social forces. Second, judged by certain practical standards such as the ability to adapt to reality by living outside of a hospital, they are less severe aberrations of behavior than are the psychoses. A third, less obvious, characteristic lies in the great sensitivity of neurotic styles of living to broad cultural trends as these differ from place to place and from one historical epoch to another.

It is this third characteristic that is the topic of my discussion. I will try to convince you of its truth first by a brief review of the recent history of the neuroses as summarized in Ellenberger (7). In the 18th century, Ellenberger tells us, women suffered from the "vapors" and men from hypochondriasis. Ellenberger attributed the disappearance of the former condition to the decline of the aristocracy, but another factor may have been the loss of popularity of the old humoral theory. Hypochondriasis became old-fashioned by the 19th century and was replaced by what was called the "wear-and-tear syndrome" (1831), attributed then to overwork, lack of exercise, and the smoky air of the cities during the Industrial Revolution. A similar disease was described in the United States in 1869 by George Beard as neurasthenia, also a disease of men. However, as neurasthenia became an increasingly popular diagnosis it came to be attributed more to constitutional factors and the malign effects of masturbation than to overwork. By the end of the 19th century the main neuroses were hysteria for women and neurasthenia for men.

The latter half of the 19th century saw the introduction of a condition later to be called phobia and destined to proliferate into a lexicographer's paradise of subtypes. Another new condition called cerebro-cardiac neuropathia entered the field and was the prototype for what was later to be called anxiety neurosis. As industrial accidents, with their resulting train of insurance claims, became common in the 20th century, the diagnosis of traumatic neurosis achieved a new prominence.

HYSTERIA

There is no psychiatric entity whose vicissitudes better illustrate the profound influence of historical and cultural forces than hysteria. First it was attributed to the peregrinations of a wayward uterus, then to possession by demonic spirits, then to hereditary degeneration of the brain, and at various times throughout its history to the influence of incompletely expressed or distorted sexuality. For the early Freud, hysteria was considered preeminently a sexual neurosis: the patient's repressed and dammed-up sexuality expressed in symbolic fashion. Although he changed his theory of hysteria in various ways, Freud continued to consider hysteria a product of the inability of the sufferer under certain conditions fully to express his genital sexual impulses (8).

However, since Freud there has been a considerable change in the way psychoanalytic workers regard hysteria. Increasingly, pre-oedipal and specifically oral elements have been emphasized; a recent review of the subject (9) described two kinds of hysteria, the oral and the phallic. The latter label is applied to individuals who do not appear to depart very far from normality, while the oral hysterics are the sicker ones. I regard this change in the way psychoanalysts view hysteria as part of a largely unacknowledged but real retreat from sexuality as the most important organizing and explanatory principle in the study of the neuroses. As is illustrated so cogently in the case of this development in hysteria, the sexuality of later psychoanalysis, in contrast to that of the early Freud, has become tame, in a sense demythologized, no longer a fierce torrent periodically overflowing its banks but rather a broad estuary covering much territory to a shallow depth but with little force and difficult to distinguish from the sea into which it flows. Or to use a differ-

ent metaphor, a dowager matron looking back with satisfaction on her hellion past.

NEUROSIS TODAY

The increasing difficulty in classifying neuroses in the 1970s is the wide variety of behavior that today is considered neurotic. If we agree to a broad rather than a narrow definition of neurosis, using as our criterion that the individual seeks psychiatric or other psychotherapeutic help for some form of nonorganic personal distress that does not seriously interfere with reality adjustment or require hospitalization, then we must include a broad spectrum of maladaptive behavior—the classical symptom neuroses: phobias, anxiety states, depressions, obsessive and compulsive symptoms, and hysterical conversion reactions; the psychoneurotic personality disorders, characterized not by distinctive symptoms but rather by persistent, aberrant overall life-styles such as the hysterical and the obsessive; and we must also include as neurotics persons who are distinguished neither by specific symptoms nor by a persistent characterizing life-style but rather by certain restricted behavior patterns manifested in their relationships with other people. There are in addition those individuals who seek psychiatric help because of existential problems such as loneliness, despair, unhappiness, lack of fulfillment, or an uncertainty in their sense of personal identity.

This alienated man is not a new arrival. He was described by Karl Marx, and we can recognize him in Melville's Bartleby. Today we increasingly have our attention called to him as the paradigm personality of our age in the form of "Protean Man" (10), who regards himself as a commodity to be marketed. With a fragile enough ego, he may even become Grinker's borderline patient (11). A reed in the interpersonal winds, he seems to feel a tropism toward whatever stronger force will lend him definition and boundaries. In an earlier age he may have sought his salvation through religion; today he seeks it through psychotherapy.

Are we to conclude that we are living in a new Age of Neurosis as the mental health of our citizens bends under the stresses of modern living? Despite doomsday cries to this effect, I think it more likely that what has changed is not so much the vulnerability to neurosis as the readiness to label as neurotic forms of personal discomfort and maladaptive behavior that previously would have been considered within the bounds of the normal.

The reasons for this extension are complex; it is a by-product of some of the same broad social, cultural, and historical tides that are responsible for the fact that we live in a different world than our ancestors of the 19th century. There are, for example, the persistent effects of that 18th-century French heresy, the idea of Progress: the conviction that man is perfectible—that all problems are soluble and that citizens are entitled not only to the pursuit of happiness, but to happiness itself. Also, since religion has lost much of its influence, many people have transferred their allegiance to the new priesthood of science and to its medical exemplars in psychiatry in order to be helped to seek their birthright of contentment and freedom from discomfort. The result is that, in spite of the fact that Sigmund Freud denied even the theoretical possibility that man is perfectible (12), psychiatrists have in a sense become "Doctors of Happiness."

Also, society has legitimized and sanctioned an expansion of the sick role, thus allowing under its umbrella the inclusion of many problems that otherwise might be considered moral rather than medical. Szasz (13) fulminated about the hypocritical aspects of this development and claimed that by transferring moral conflicts into the domain of medicine, and by welcoming the victims of such conflicts into the consulting rooms of psychiatrists, society has evaded its responsibilities to deal effectively with the social conditions that produce these problems. We have in a sense substituted motivation for morality, so that attitudes and kinds of behavior that previous generations would have taken at their face value now fall under psychoanalytic scrutiny and become examples of neurosis. A recent report of the GAP Committee on Child Psychiatry (14) pointed out that the concept of emotional illness was not used with respect to children until 1925; before that time children were not supposed to suffer from any psychological complaint except mental deficiency.

It is not only psychiatrists, with their neurotic caseloads, who feel the impact of the forces I have been describing. Physicians generally—especially those of first resort like general practitioners and internists—have noted the considerable number of patients who consult them not with well-defined and clear-cut illness but rather with vague complaints that often can be seen as serving as a vehicle for personal or social disabilities.

DIAGNOSTIC LABELING

The consequences of the widened view of neurosis are profound. First, what are its effects on diagnostic labeling in psychiatry? I am aware that the practice of attaching labels to complicated states of human distress is viewed in certain quarters with something close to contempt. However, if for no other reason than the recent increase in health insurance arrangements, psychiatrists who elect to receive their fees through insurance must act like doctors sufficiently to make medical-model diagnoses (15). But with the best will in the world it is often very difficult for psychiatrists to find appropriate diagnostic labels for some neurotic patients they are treating. What diagnosis is to be made, for instance, of a man who comes for treatment for the very good reason that he finds himself chronically restless and dissatisfied and recurrently involved in interpersonal situations in which people become fed up and irritated with him, thus jeopardizing both his marriage and his career? There is no question of psychosis in this case and although he may display certain characteristics of, say, the obsessive personality, the better one gets to know him the less one is satisfied with such simplistic generalizations. What often actually happens

in such cases when insurance reporting is involved is that the psychiatrist will mark down "depression" or "anxiety neurosis," knowing that this is really a very inadequate way to characterize the human being he is dealing with.

And what about treatment of the psychoneuroses? The model for exploratory rather than supportive psychotherapy has been based on the assumption that improvement takes place as a result of insight through derepression. However, this model does not seem to work very well in many of the cases I have been describing, since for these patients the unconscious seems to have lost a good deal of its mysterious and noxious quality, while the developmental arrest that has left them emotionally handicapped may have been due to the fact that they were *deprived* of certain experiences rather than having had to *repress* pathological experiences (16). In a way, they seem to be attempting to change their future without undoing their past; this causes difficulties for therapists whose training has pointed them toward the latter mode of therapy.

EVALUATING RESULTS

When we come to the questions of establishing criteria for evaluating the results of psychotherapy, we again find that the new kind of neurotic caseload has compounded this difficult task. The removal through psychotherapeutic help of a specific and definite symptom like a phobia or a counting ritual, although it may have been only part of the story, at least afforded a clear-cut basis for determining whether or not the treatment had been successful. However, now that such symptom neuroses are in the minority, success or failure in psychotherapy must be gauged more by attempting to evaluate the sometimes vague and even utopian goals of total personality change. Therapy operating on this basis runs the risk of becoming a matter of subjective agreement of patient and therapist, with all the attendant possibilities of transference-countertransference distortion.

It seems to me that we have come full circle from Cullen's time. Our "neurosis" is as much a mixed bag as his, although where his included medical, neurological, and psychiatric disorders, ours contains a heterogeneous stew of psychological, social, moral, and existential ingredients. Today the usefulness of neurosis as a categorizing label has become compromised; perhaps styles in neuroses have changed to such a degree in the 1970s as to raise real questions about whether the term ought to be retained at all.

Changing Styles in Psychoses and Borderline States

BY ROY R. GRINKER, SR., M.D.

CLINICAL PSYCHIATRISTS HAVE OBSERVED unmistakable changes in the form and content of neuroses and psychoses during at least the last 20 years. For example, at both Michael Reese Hospital and the Illinois State Psychiatric Institute during 1970 only 1.70 percent of the patients were manic, 0.63 percent were catatonic, and only two percent of those with organic brain diseases were diagnosed as psychotic. Unfortunately we have no adequate comparative statistics from past years nor do we know if the absolute numbers of psychotic schizophrenics or manic-depressives have changed. But we can document the changing form of what we see. The psychoses are shorter lasting, less detached from reality, and less dramatic.

How can we explain these phenomena? It has been suggested that the antischizophrenic and antidepressant drugs have affected the form and course of psychiatric entities. However, the psychoses developing even before the legitimate use of drugs are less dramatic than in earlier eras. In our investigations of young first-break schizophrenics we have observed that the acute psychotic break is short-lived and that the subjects remember and honestly recount the details of their delusions or hallucinations. On balance these patients revealed more affect than usually described. They were depressed, lonely, and devoid of feelings of pleasure, with relatively little cognitive disturbance or associative slippage. They seemed in general to recognize their social limitations and seriously attempted to adapt to their schizophrenic process.

In the psychotic we are always concerned with how much the premorbid character and personality influences, modifies, or covers the basic psychological disturbance. We are concerned with the effect of the cultural matrix—how much of the psychosis is cultural-fair or cultural-free (17)—and what is the threshold for tolerance of deviance within the subject's social group? Finally, there is an astonishing difference in diagnoses made by psychiatrists from various countries. For example, schizophrenia is diagnosed much more frequently by American than by British psychiatrists, who in turn diagnose manic-depressive psychoses more frequently. The logical conclusion seems to be that we pay more attention to the cognitive defects in schizophrenia, recognizing that the affective component is an early and often predictive element in the schizophrenic process. The English pay more attention to the depressive and anxious phases and hence diagnose affective disturbance more frequently.

CAUSES OF PSYCHOTIC BREAKS

To explain the changes in the psychoses observable during the last several decades it is necessary to define the factors involved in the multicausality of psychotic breaks. I will list a few.

Biogenetic. Modern techniques for the study of chromosomal aberrations have not progressed sufficiently to isolate genic differences, even in those syndromes for which clinical evidence suggests a biological component. But there is some evidence that manic-depressive syndromes (either unipolar or bipolar) reveal a family his-

tory and are linked to other genetic faults. Recent work has indicated that the schizo-affective syndromes are related to family histories of depression.

On the other hand, the percentage of schizophrenic syndromes in monozygotic twins has dropped considerably since Kallmann's original studies. But high-risk children, whether raised by biological or by adoptive parents, develop schizophrenia with greater than expected frequency.

None of the neurotic syndromes or others such as the borderline, delinquency, or drug abuse syndromes have so far revealed any biogenetic factors. However, the high incidence of such conditions in the families of diagnosed schizophrenics raises a question about the existence of biogenetic factors; that is, they may represent varying phenotypes of the schizotypic genotype. It would indeed be surprising if profound changes in the genetic pool occurred in the last two or three decades to account for changes in any of the psychiatric syndromes. In fact, the decrease in the state hospital population (mostly schizophrenics) began several decades before the advent of the phenothiazines. These drugs have decreased hospital stay, but readmissions have increased.

Child rearing. Practices vary within ethnic groups, as Spiegel (18) has shown, but the most significant changes are general and cut across all groups. These include a decrease of the extended family, absent working mothers, greater freedom and independence for the child, and less conformity to rules and regulations.

Family. Much has been written recently concerning family dynamics, their internal and external systems of communication, decision-making processes, and the "scapegoating" of one family member. Some of these theoretical concepts have taken hold temporarily but careful empirical research has negated the application of most of them; the findings, however interesting, have yet to demonstrate the precise causal link to the changes we have observed.

Social system. Our social environment has been changing rapidly. Hysterical conversion symptoms practically disappeared with the increased sophistication of the population, especially with respect to sex. Changes in technology have affected the content of paranoid delusionary symptoms and hallucinations. Our society has altered its view of behavior: in general there is a higher tolerance of deviance. More escape valves now exist for aggressive behavior and rebellion against conformity in the communes than have existed since the closing of the western frontier. It is possible that the dramatic acting-out characteristics of excited psychotics are now hidden from public view but exist as part of the youth culture.

Cultural. This factor concerns the firmness with which institutional controls are internalized within the individual and the general cultural attitude toward deviant persons. The profound regressions that we used to see are now considered "social breakdowns" rather than an intrinsic part of the psychotic process. With the advent of more humane treatment in most state hospitals, the kind of profound regressions that 20 years ago were common are now rare.

SOME SPECULATIONS

Since one can make no definitive statements about the causes of the decrease in extreme and bizarre types of psychosis, one is forced to speculate. Nonhospitalized or discharged schizophrenics seem to maintain hope and are oriented toward rational, active strivings. Young schizophrenics interviewed during their first breaks openly recount accurate details of their delusions and hallucinations. For many of them there are subcultures within the general society in which they can live relatively unnoticed. In communes and in the drug culture, with their general permissive attitudes, schizophrenics can live without psychotic-precipitating stimuli.

It seems to us that the schizophrenic tends toward psychosis not only in alienation from the self but also alienation from his stressful world. As described by Deikmann (19), he retreats from angry action. As a result his own boundaries become blurred and the external world is not integrated. The receptive mode dominates and he becomes aware of his own individual fantasies or presentational thinking in the form of hallucinations. In this phase his psychosis is peaceful and mystical but not dramatic, because he avoids aggressive action. When he attempts to reorder this form of thinking he may become paranoid and destructive, very much like the user of LSD on a bad trip (20).

If the action mode were completely abolished there would be no corrective proprioceptive feedback (21), and the internal world would be in uncontrolled chaos. However, the schizophrenics studied by our research groups have not relinquished action to an absolute degree; most of them actively and hopefully attempt to find their place within the common culture.

Our research group has observed that self-acceptance of psychiatric disability facilitates adjustment to the deficit. ("I am a schizophrenic; I know my limitations and I have lower expectations.") Adaptation to the sociocultural mainstream by lowered ideals, isolation when necessary, and membership in groups with common problems are methods adaptive to one's defects. It is as if schizophrenics learn how to be schizophrenics within the common culture. They also recognize their dependency on medication and clinics.

What all this means is that we have a changing phenomenology in deviant personalities and psychoses. However, articulation with biological, sociological, and cultural systems is not yet possible. I am sure that the changes are not artifacts in diagnosis or labeling. But the how and why are still unknown.

Changing Styles in the Treatment of Schizophrenia

BY OTTO A. WILL, JR., M.D.

"IF YOU CANNOT BEAR THE SILENCE and the darkness, do not go there; if you dislike black night and yawning

chasms, never make them your profession. . . . Seek out the sunshine . . . avoid the darkness" (22).

This statement by the anthropologist Loren Eiseley could be a cautionary note to those who engage in psychotherapy in general and in the treatment of schizophrenic people in particular. The disorder has been looked upon as mysterious and dreadful, its nature undetermined, its outcome dismal, and its treatments multiple and generally unsatisfactory. The psychotherapeutic enterprise has been marked by qualities of caution, fear, and hopelessness, suggesting that personal involvement with the schizophrenic person is forbiddingly dangerous.

The term "psychotherapy" as used here refers to the planned employment of the human relationship in an effort to bring about desirable changes in someone troubled in his living. Treatment is an ongoing process during which particular goals suited to the needs, capabilities, peculiarities, and opportunities of the patient are recognized, defined, and sought. In general terms the goal is the attainment of a form of personal freedom in which the major aspects of the self are available to awareness and recognized as being a part of one, the ways of relating to others are known, the aloneness of existence is accepted without resort to restrictive mythologies, interpersonal attachment and separation are understood as necessary and inevitable, change and uncertainty are tolerated, and choices can be made from those options for action which may be open. Therapy in this sense is not simply a technique applied impersonally to an object, but is an interpersonal transaction directly involving two or more people and, indirectly, the psychic representations of many more; it is concerned with events of the past and the present, and with expectations of the future. It is a part of the society and the culture in which it takes place.

PERSONAL EXPERIENCE AND THE CONCEPT OF SCHIZOPHRENIA

When I was growing up in a small western town there was locally no great sympathy with or understanding of mental disorder. Mild deviations from the established norm were acceptable, and some instances of "feeblemindedness" and supposedly harmless craziness were tolerated. Much of what we might now call psychiatric trouble was denied, named something else, laughed at, whispered about, hidden away, or driven out of the community. We didn't talk very much about these matters because we were ashamed and afraid; they were associated with dirt, weakness, and some kind of personal inadequacy—as were venereal diseases and even tuberculosis. The afflicted person was looked upon as dangerous or loathsome; if he did not rapidly abandon his deviancy he was likely to be "put away," an act often concealing the wish to destroy him.

As a student in college and medical school I found similar attitudes despite our efforts to be more objective and understanding. Associated with the patient were feelings of awe, disgust, fear, mystery, and (for some) fascination; he often appeared to be untouchable, a social leper, an object whose peculiar behavior might be without meaning or purpose and could be put on display or demonstrated by the learned for the edification of those relatively untutored.

In the medical tradition psychiatric conditions had come to be looked upon as disease: emphasis was placed on biologic-genetic events rather than on interpersonal-social-cultural phenomena, or a useful combination of these. But the difficulties of treatment and the social deterioration evidenced in prolonged institutionalization contributed to the disorder's being looked upon as a "living death." The opening of the door to psychotherapy was hindered by the idea that the patient could not readily establish a transference (a relationship) and that disaster might result from persistent attempts to form one.

The patient did not fit well into the medical model. In the large psychiatric hospitals the inhabitants lived marginal existences, their needs for food, shelter, clothing, and humane care frequently met inadequately. In those days—at least where I worked—the psychiatric residency was not popular; it ranked below surgery, medicine, and pediatrics. If you went into psychiatry, you were likely to be thought of as being a bit odd or something of a failure.

My interest in psychiatry declined as my early education in the field increased. The patient seemed to be something of an outcast, and I feared that by association with him I might find a similar fate. Just as I was getting to be a little comfortable in my new role as a physician I didn't welcome dealing with people who were unable to accept me in that role. I had learned to deal with a person professionally and as something of an object. I "took" a history, I "made" a diagnosis, I "gave" treatment, and I "administered" medicine. There was nothing in my education that enabled me to listen and to talk simply with another person. In psychotherapy the patient didn't assume a proper stance vis-à-vis mine, and as a result I felt uncomfortable and unappreciated; I didn't want to lose the still fragile security that I had found in being a "doctor."

For some years I dealt with large numbers of patients, having little time for any one person. I sought to produce change without knowing the nature of the condition to be changed or the goal desired, except for its superficial resemblance to conventional "adjustment." I was familiar with the use of insulin, Metrazol, electroconvulsive therapy, prolonged sleep, hydrotherapy, barbiturates, lobotomies, and so on. Displeased with myself and the task, I sought release by labeling myself unsuitable and the task too difficult, if not impossible.

Circumstances then led to my having the opportunity to spend a great deal of time with a withdrawn, mute patient who had failed to respond to a variety of treatments. Of necessity I put aside the paraphernalia of my ordinary medical work and found that I must listen and observe but for the most part not to otherwise act. No miracles were achieved but the patient became a person to me, and he showed me aspects of myself that were discomforting. Through personal therapy I looked as best I could at my own background, motives, values, and goals,

and I realized that what I saw could be on occasion useful if not pleasing. The schizophrenic patient was of particular interest as he persistently challenged any tendency to feel that one had "found the answer." Of greatest importance to me was the idea that to be psychotic was not to be somehow inhuman. As I came to know the patient as a person he was found to be in significant ways like myself, a finding applicable to all "strangers" and of increasing value in a world of easily breached national boundaries.

MAJOR DEVELOPMENTS IN THE PAST 50 YEARS

There have been a number of developments in psychiatry during the past 50 years that have enlarged the concept of psychotherapy, particularly as applied to schizophrenia. I will note briefly those which have influenced me to the greatest extent.

Patients. If one can keep some of his wits about him and not succumb too readily to anxiety and those forms of behavior designed to reduce its discomfort, he can learn best from intimate contact with patients. Many students have the opportunity to observe large numbers of patients, but only a few have the privilege of spending long periods with any one person. When one meets day after day with a patient, setting himself to observe what goes on, much of great interest about the transaction is likely to be revealed.

Teachers. One's own observations and learning may be limited by certain personal qualities, by anxiety, and by lack of professional contact. The student needs the teacher, revealed through personal association as well as writings. For me there were Hilde Bruch, Dexter Bullard, Frieda Fromm-Reichmann, Lewis Hill, Harry Stack Sullivan, and others. From them I learned that there was much that I had seen but not recognized and that hard work, some clear thought, persistence, and compassion can accomplish much in situations prematurely labeled hopeless.

The milieu. Studies of the environment in which the patient lives emphasize that psychotherapy is not carried on in a social vacuum. Since the work of Sullivan in the 1920s, increasingly systematic studies have been made of the social structure of institutions, and attempts have been made to define and sort out the antitherapeutic from the therapeutic influences (23).

The family. Studies of family relationships have demonstrated that these are influential not only in terms of the past but also the present and the future. Family members could no longer be ignored, dismissed as "bad," or accepted as "good"; they had to be considered in the planning and carrying out of any serious therapeutic effort.

The field. Psychiatric disorders, once thought of as reflections of disease within a person, came to be viewed by some observers as phenomena operating within a social field or interlocking biological, social, and cultural systems. The patient's behavior could be thought of as an attempt to deal with a total life situation, including past experience as a molder of personality, present influences, and expectations of the future. The growth of a variety of "therapies"—family, group, milieu, and social, in addition to psychoanalytic and interpersonal—reflects the increased concern with the human relationship as a vital factor in human development and survival.

Ethology. Studies of animal behavior are potentially useful if one keeps clearly in mind the fact that man is man and is not to be comprehended through careless translations of observations of fish, birds, dogs, wolves, and so on. Man's instinctual resources seem to be less than we thought some years ago; what he is reflects the interweaving of his biological substrate with social-cultural influences and interpersonal experience.

Throughout these past 50 years the field of psychiatry has been greatly expanded. Developments in anthropology, sociology, religion, and philosophy, as well as in biochemistry, neurophysiology, and pharmacology, have been recognized as relevant to our work. The psychiatrist, inevitably involved in human living in multiple ways, has knowledge too valuable to be restricted to the consulting room and to those officially designated as patients. The rapid growth of the concept of community psychiatry is evidence of the recognition of this idea.

CONCEPTS OF SCHIZOPHRENIA

Relevant to the psychotherapeutic procedure is the therapist's concept of the difficulties with which he is working. As a therapist my current view of schizophrenic phenomena includes the following ideas.

The schizophrenic problem, greatly simplified, is that of maintaining required human relationships without the experience of intolerable anxiety. An intense relational bond was formed in infancy with the mother and in the family. There also was found insecurity to the extent that relationships could be maintained only through such distorting devices as dissociation, denial, and obsessional substitutions.

The schizophrenic phenomena with which I am concerned appear in florid form in adolescence, a time of great demand for growth, increased interpersonal intimacy and self-revelation, and separation—from places, people, ideas, values, and concepts of the self. For one whose sense of identity and personal security has been uncertain and fragile, such demands are difficult to face without the arousal of great anxiety.

The essential schizophrenic condition is a state of panic and personality disorganization demanding rapid resolution. The psychotic performance, despite its seeming craziness and incomprehensibility, is a response to conflict, an attempt to solve a problem, and is goal-directed. The problem is vital to continued existence. How can you hold on to relationships required for survival without becoming so insecure that you become "crazy"? The schizophrenic answers include the oversimplified and difficult-to-modify hebephrenic and paranoid "solutions," the rebuilding of defenses with a further limiting of possibilities for creativity and growth, and changes ac-

complished by insight and the ability to profit from new experiences.

PSYCHOTHERAPY OF SCHIZOPHRENIA

I am not so much concerned with the styles of psychotherapy as I am with aspects of the experience that may be less subject to fashionable variation. Among the principles of treatment are the following:

1. As the disorder itself is not meaningless and unrelated to human experience, it can be dealt with in ordinary terms.

2. Relational bonds will develop as the result of frequent meetings of patient and therapist, and these ties will be intensified if the meetings are accompanied by emotional arousal. The relationship can be useful or otherwise; the observable details of the involvement are what we know as technique.

3. The therapist need not be "perfect"; he will make mistakes and he will have exposed in himself a wide range of feelings. None of these—mistakes and feelings—can he deny; he must be aware of them and use them wisely, but he will rarely be certain as to the rightness of his acts.

4. The therapist should have or acquire certain abilities, among which are taking pleasure in the growth of another person; tolerance of attachment, dependency, and the inevitable stress of separation; the strength to set limits and yet permit another person to live in a way of his own; and the capacity to cooperate with members of a team, enduring the accompanying envy, jealousy, competition, anger, and affection. Finally, he should be able to accept the often slow pace of growth.

Landlord-Supervised Cooperative Apartments: A New Modality for Community-Based Treatment

BY CHING-PIAO CHIEN, M.D., AND JONATHAN O. COLE, M.D.

A landlord-supervised cooperative apartment program—a new type of community residential treatment modality—was developed through the collaborative effort of a state mental hospital, the Massachusetts Department of Public Welfare, and citizens as landlords. The authors make a number of comparisons between this modality and more conventional facilities such as halfway houses, family care homes, nursing or rest homes, and independent apartments or rooming houses. They conclude that in a community such as the one described this modality appears to be financially and logistically superior to the others.

MANY HOSPITALIZED PSYCHOTIC PATIENTS can live and function in the community if a suitable sheltered environment is provided and appropriate aftercare plans are adopted. The conventional facilities used by psychiatric hospitals to meet the needs of such patients are halfway houses, family-care homes, nursing homes, and independent apartments or rooming houses.

All these facilities have limitations: therapeutic, financial, or both (see table 1). Halfway houses are arduous to establish and expensive to run and usually provide for only a few patients at a time. In Massachusetts, family-care homes are costly to the Department of Mental Health and provide a setting that sometimes promotes dependency on the foster parents. Nursing homes are often little better than chronic hospital wards and are therapeutically inappropriate for younger or better integrated patients involved in work or rehabilitation programs. Independent apartment living or rooming houses, even if they are subsidized by welfare or a charitable group, may be too big a step for many patients and can be difficult to launch because of the expense.

The Cooperative Apartment Program at Boston State Hospital is a collaborative effort on the part of state agencies and a concerned community to prevent indefinite institutionalization of the long-term mental patient. It grew out of an inpatient remotivation program for chronic patients and evolved into a useful and steadily expanding activity that has proved to have therapeutic, logistic, and fiscal advantages over more conventional programs.

In 1967 substantial progress was made in improving the psychiatric status and social competence of a growing group of chronically hospitalized patients at Boston State Hospital. Although it was felt that many of these patients were ready to live outside the hospital, the majority either were homeless or their families were unable to accept them. The one halfway house affiliated with the hospital viewed these patients as "too chronic," and all family-care placements were filled. But the patients were doing too well to be relegated to nursing homes.

In response to this problem one of us (C-P. C.), aided by a hospital staff member who owned a three-family home, approached the Massachusetts Department of Public Welfare. The staff member was willing to rent one unit in her home to ex-patients and provide them with supervision and help as they learned to function in the community. The chief mental health coordinator of the Welfare Department, intrigued with the idea, encouraged the local welfare office to provide a liaison worker to help plan and expedite the new arrangement. A rate was established ($20 a week a person for housing and supervision) that enabled the landlord to provide a comfortable furnished apartment for four to five patients.

DESCRIPTION OF THE PROGRAM

The Boston State Hospital Cooperative Apartment Program is unique in that it depends upon the joint efforts of the hospital, the Welfare Department, and citizens in the community. The area immediately surrounding Boston State Hospital is well provided with three-decker houses (buildings consisting of three one-floor apartments) and is a low- to middle-class area. Normally the patients live in one apartment in the house, the landlord lives in another, and the third is rented to someone else. A patient, like any citizen, can live in the apartment for as long as he wishes. Landlords owning these three-decker houses who are willing to house and supervise patients are recruited into the program through various means. The competence of the landlords who apply to be supervisors is evaluated by the psychiatric staff of the Cooperative Apartment Program, and a physical evaluation

Drs. Chien and Cole are with Boston State Hospital, Boston, Mass. 02124, where Dr. Chien is Director of Clinical Research and Dr. Cole is Superintendent. They are also with Tufts University School of Medicine, Boston, where Dr. Chien is Assistant Clinical Professor of Psychiatry and Dr. Cole is Professor of Psychiatry.

TABLE 1
Comparison Between Institution-Based and Community-Based Treatment Facilities for the Mentally Handicapped

Category	Mental Hospital	Nursing Home/ Rest Home	Conventional Halfway House	Boarding House/ Independent Apartment Group Living	Foster Family Care	Landlord-Supervised Cooperative Apartment
Establishment cost* to funding agency	More than $1,000,000	More than $100,000	$40,000–80,000	Less than $1,000 (furniture)	—	—
Annual maintenance cost* per patient	$ 10,307	$ 6,195	$ 3,000–4,000	$2,000–3,000	$2,500	$2,183
Annual savings per patient compared with patient cost in state mental hospital	—	$ 4,112	$ 7,307–6,307	$8,307–7,307	$7,807	$8,124
Status of occupant	Patient	Patient	Resident	Resident	Resident or patient	Resident
Availability of supervisor	Yes	Yes	Yes	Usually not (high recidivism)	Yes	Yes
Promotion of dependency	Yes	Yes	No	No	Yes	No
Limited length of stay	Yes/No	No	Yes	No	No	No
Citizen participation in daily care	No	No	Yes	No	Yes	Yes
Reintegration into community	No	No	Yes	Yes	Yes	Yes

*Costs are approximate, based on Massachusetts figures for 1972.

of the apartment is made by the City of Boston Housing Inspection Department. Applicants should demonstrate their active concern for the rehabilitation of the patients and be free to meet the many demands of time and energy involved in daily supervision.

Under the care and supervision of the landlord-supervisor, the patients are responsible for such routine chores as cooking, housekeeping, shopping, and laundry. The apartments vary somewhat in the degree of autonomy assumed by the tenants. However, the general practice is for the landlord to be actively supportive in the beginning by providing meals and assistance to the tenants but to work gradually toward having them care entirely for themselves. If the tenants want to have the landlord cook for them because of their work schedule or for other cogent reasons, the rent is increased to include the cost of meals. Patients who are without financial resources upon their release from the hospital are supported by the Welfare Department through the Disability Assistance category. The patient receives the check in his own name and is expected to handle his own budget. Most patients pay $80 a month to the landlord-supervisor for room and care.

Most of the men and women considered for the program are long-term patients who are capable of maintaining responsibility for at least a minimum of personal care, regardless of whether or not they have psychotic symptoms. Once they have moved into an apartment, their supervision is carried out by both the landlord and the Cooperative Apartment Team, which consists of a psychiatrist, a social worker (from the local welfare office), an occupational therapist, and a nurse. All apartments are visited at least once a week by the team to discuss any problems, and staff members are available by telephone to both tenants and landlords around the clock. In addition to the supervision provided by the Cooperative Apartment Team, the hospital unit that referred the patient to the program retains responsibility for treatment so that continuity of care is assured.

All of the tenants in the cooperative apartments are expected to engage in daytime activity programs consistent with their functional level, either at work or in the day-care program at the hospital. Currently, 16 percent of the patients are employed in community industry and 55 percent in the sheltered workshop program at the hospital. Most of the remaining 29 percent, either because of age or low functional capacity, attend day-care programs at the community lounge located on the hospital grounds. A few tenants remain in their apartments doing housekeeping and other small jobs.

Medication

For many of the patients who need to be maintained on medication a long-acting phenothiazine (fluphenazine enanthate) is used; it is inexpensive and reliable. The patient is expected to come to the hospital treatment room to receive his injection on a scheduled date. If he does not show up within 48 hours, the staff nurse goes to his apartment to administer the medication. Although emphasis has been placed on the need for maintenance medication, efforts are also being made to help the tenants phase out their drug use.

Two research projects to study refinement of the maintenance use of depot phenothiazines are being carried

TABLE 2
Evaluation of the Program by Patients

Questionnaire Statements	Yes N	Yes %	No N	No %	Uncertain N	Uncertain %
1. Life in the apartment is better than life in the hospital.	54	93.1	3	5.1	1	1.8
2. I have been helped by living in the cooperative apartment.	54	93.1	1	1.8	3	5.1
3. I would like to stay in the cooperative apartment.	53	91.4	2	3.5	3	5.1
4. I would like to continue living in the cooperative apartment rather than return to the mental hospital.	52	89.7	3	5.1	3	5.1
5. Since I moved from the hospital to the apartment I feel more like a human being.	54	93.1	3	5.1	1	1.8
6. I would like to see more patients move into cooperative apartments rather than stay in the mental hospital.	48	82.7	3	5.1	7	12.2

out (1, 2). One study (1) has clearly demonstrated that the common practice of using antiparkinsonian medication prophylactically is unwarranted. Even though the incidence of extrapyramidal symptoms in this study was relatively high, the symptoms could be controlled by antiparkinsonian medication as needed. The other study is exploring the feasibility of intermittent drug therapy at a rate determined by the patient's own judgment. This is extremely important in light of the severe side effects frequently reported with long-term maintenance drug treatment. During long-term fluphenazine enanthate treatment, one of us (C-P.C.) noticed a sensory type of akathisia in a few patients. This has been described by the European school as "cenesthopathia" (3)—"a general feeling of being ill." It can be managed by the doctor's reassuring the patient, by reducing the dosage, and by antiparkinsonian medication. Too often fluphenazine enanthate is discontinued because of cenesthopathia, which often makes the patient feel panicky, as well as a misconception on the part of the physician that the patient is relapsing.

CURRENT STATUS OF THE PROGRAM

From the modest beginning in December 1967, a total of 35 apartments have been established by the team. Over this four-year period, 12 of the apartments have been closed: seven due to landlords' personal reasons and five because of substandard supervision. Despite the closing of a few apartments every year, the total number of apartments available for ex-patients has been steadily increasing. At the present time, 23 apartments are available to 101 ex-patients.

As of May 1972, a total of 186 homeless patients, mostly chronic schizophrenics, have been placed in the cooperative apartments. Thirty-three out of these 186 patients (18 percent) have been returned to the hospital because of an exacerbation of symptoms or drinking problems. This suggests that more than 80 percent of such homeless patients who because of lack of income or social resources might otherwise have been continuously confined in the institution could be successfully placed in the community. About 90 percent of the patients accommodated in the cooperative apartments were receiving welfare assistance at the time of placement. Currently the cooperative apartments are also open to younger and more acute patients from the mental health centers covering the Boston State Hospital catchment area. Twenty-eight such patients have been placed since July 1, 1971. Five patients have been accepted into this program as "halfway-in" patients from the outpatient clinic; the purpose was to avoid unnecessary hospital admission.

IMPACT ON THE COMMUNITY

The Cooperative Apartment Team has maintained a good working arrangement with the landlords, and problems are usually ironed out quickly. As a result, landlords tell their friends and neighbors about the program and new landlords are recruited quite easily. Obviously a financial incentive exists. With four patients residing in an apartment, a landlord's income from this source ranges from $320 to $400 a month. The resistance often encountered by halfway houses when they try to move into a new neighborhood has never been an issue in this program. In fact, once the neighbors see how well former mental hospital patients adapt to the community, they are usually more than willing to give their assistance and often try to find out about the program for themselves. The close supervision given the patients by the team and the landlord's everyday participation in the program bring some assurance to the landlord that rent will be collected regularly, that there is a continuity of tenants, and that their property will be maintained.

Barrett and associates (4) reported that the community tenure of chronic patients following emergency discharge was more strongly related to the characteristics of the caretaker than to the psychopathology of the patients. Families that were financially disadvantaged often kept patients on as useful helpers in their homes. A similar situation has been observed in our Cooperative Apartment Program. The landlords in this program are usually hard workers, often engaged in more than one full-time job. It is the wife of the landlord who actually cares for the patients. Helping the patient to relearn community skills and daily household chores on the landlord's own premises is both rehabilitative for the patient and practical for the landlord. Thus this program attracts landlords who often have difficulty with regular tenants who are sometimes delinquent in their responsibilities.

The area surrounding Boston State Hospital, where almost all the apartments are located, is caught up in the urban crisis described in Banfield's *The Unheavenly City* (5). Community residents are often unaware of the help they can receive from public agencies; conversely,

public agencies sometimes are too overloaded to actively approach community residents. A program such as the Cooperative Apartment Program brings these two segments of society together to the benefit of each. Because the psychiatrist, nurse, and social worker make weekly visits to all the apartments, the landlords in particular and the community in general see them as people who want to help them rather than as uncaring professionals hidden away in far-off offices. This provides community members with easier accessibility to help from these professionals when they need it. Aside from the team, workers from various other human service agencies are brought in to aid in rehabilitating the patients living in the cooperative apartments. This indirectly results in a strengthening of the rehabilitation of the core city itself.

AN ATTEMPT AT EVALUATION

As described by Mechanic (6), the effects of a new mental health program such as the Cooperative Apartment Program can be evaluated in at least three ways:

1. What is the subjective response of patients to the program? Do they feel they have been helped, have fewer symptoms, and are more able to cope?
2. What is the objective evaluation of the patients' performance and the quality of their lives after exposure to the program?
3. Does the program lead to an equivalent or better outcome at less cost than other programs?

In order to answer the first question, patients who have lived in an apartment for three months or longer were asked to complete a questionnaire covering six areas of concern. Table 2 shows the results. From 82.7 percent to 91.3 percent of the patients endorsed the program with enthusiasm, while approximately five percent of them had negative responses.

To answer the second question, an objective evaluation by the landlord-supervisors was carried out by means of a seven-point global rating scale ranging from "very much worse" (score = 1) to "very much improved" (score = 7). The landlords were asked to evaluate a patient's current behavior compared with his behavior when he first moved into the apartment. The results showed that all the tenants were considered "much improved" to "very much improved" in five areas important to community living: mental condition (average score of 6.34); housekeeping skills (6.33); personal hygiene and good grooming (6.41); personal relationships (6.37); and adjustment to community life (6.41).

Regarding the third question, the cost of the Cooperative Apartment Program is the lowest among a number of programs, as shown in table 1. The annual cost per patient of $2,183 is composed of $1,788 from the Massachusetts Department of Public Welfare Disability Assistance category and $395 attributable to the state hospital staff and space costs. Seventy-five percent of the Massachusetts Disability Assistance cost is reimbursed to the state from federal resources; therefore the actual cost to the Commonwealth of Massachusetts is $447 plus $395, or $842 for each patient per year.

CONCLUSIONS

The Cooperative Apartment Program, a new type of community residential program, is a hybrid of foster family care and independent apartment living. With supervision provided by the landlord living in the same building but on a separate floor, the patient can enjoy a family atmosphere yet maintain some privacy and independence. Because of the landlord's participation in this program the resistance of neighbors, often observed in the establishment of halfway houses, can be eliminated. The availability of cooperative apartments makes the life of homeless mental patients more natural and gives them a chance to adapt to community life while they are still under supervision. The developmental potential of this program—financially, socially, and administratively—is much greater than that of traditional halfway houses. Evaluation of the program revealed a remarkably high degree of satisfaction on the part of both the clients (patients) and caretakers (landlord-supervisors and hospital staff). The costs were about a fifth of the amount required for hospital-based treatment.

Rehabilitation of the ex-mental patient within the core city helps to improve the urban situation by bringing concerned and knowledgeable professionals into the community. The expansion of this program will undoubtedly help to shift the traditional health delivery system for the mentally handicapped from the back wards of institutions to a more humanity-oriented community basis.

Screen Memories in a Pair of Monozygotic Twins Discordant for Involutional Depression and Psychophysiological Disorders

BY LORETTA R. LOEB, M.D., STANLEY PEAL, M.D., FELIX F. LOEB, JR., M.D., AND BRYCE TEMPLETON, M.D.

The authors studied a pair of monozygotic twins who became discordant for mental and physical disorders late in life. Differences in the twins' early histories, earliest memories, and reactions to the loss of their mother when they were children suggest that their early interactions with their environment resulted in different modes of adaptation, which subsequently became internalized as different defensive and characterological patterns. The authors believe that the specific environmentally determined psychodynamic influences described in the paper serve to explain the twins' discordance for disease.

IN 1876 GALTON (1) INTRODUCED the method of comparing the life histories of monozygotic and dizygotic twins to study the hereditary determinants of disease and concluded that "nature prevails enormously over nurture." When others began to use more refined methods to study twins, Galton's conclusion was confirmed, and the single twin-pair study method has contributed greatly to our knowledge of the interrelationship between heredity and environmental factors in the etiology of both physical and mental illnesses. George Ham (2) said that the modern dimension of investigation of genetic dynamics and psychodynamics as interacting and mutually dependent factors will become an outstanding factor in our search for truth in the field of human behavior and psychiatric illnesses.

Our paper is an effort in this direction. We describe a pair of identical twins who are discordant for involutional psychotic depression, diabetes mellitus, and coronary insufficiency. At the age of 59 the older twin, A., developed an involutional psychotic depression and diabetes mellitus. At the age of 60 the younger twin, B., developed a coronary insufficiency. B. never developed an involutional psychotic depression or diabetes mellitus, and A. never developed coronary insufficiency. Differences in the twins' birth weight and earliest memories suggest a nongenetic explanation for these discordances.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors have all been with the University of Pittsburgh School of Medicine, Western Psychiatric Institute and Clinic, Pittsburgh, Pa., where Dr. Loretta Loeb was Assistant Professor of Psychiatry, Dr. Peal is Assistant Professor of Psychiatry, and Dr. Felix Loeb was Clinical Associate Professor of Psychiatry. The Drs. Loeb are now in private practice at 1250 Prospect St., #C-25, La Jolla, Calif. 92037. Dr. Templeton is now on the staff of the National Board of Medical Examiners, Philadelphia, Pa.

The authors wish to thank Richard Iammarino, M.D., for his help in analyzing and interpreting the red blood cell antigen data, and Larry V. Pacoe, Ph.D., for his assistance with the psychological testing.

METHOD

The monozygosity of our twins was established by the fact that they had identical blood types including the rare R_2R_2 factor (Weiner) and similar lipoprotein electrophoretic patterns and were identical in appearance, voice, nailbed structure, and tooth conformation (3). The clinical evaluation of each twin included a history, a physical examination, a review of hospital records, a videotaped psychiatric interview, and psychological tests. The psychological tests performed included the Rorschach, the Human Figure Drawing, and the Minnesota Multiphasic Personality Inventory.

RESULTS

Significant Family Medical History

The twins' father and three brothers died of heart attacks. The father and one brother were alcoholic. A second brother had been hospitalized for involutional psychotic depression. A third brother suffered from diabetes mellitus.

Early History of the Twins

The early history of the twins was obtained largely from an older brother, C. The twins were the fourth and fifth of eight sons born to first-generation immigrants. A. was born first and was slightly heavier. B., unlike his twin, was a "little devil," and was very attached to their mother.

When the twins were seven, their mother died from peritonitis seven days after childbirth. She was described as a "lady" who was outgoing and aggressive and who had many friends. She was "stern, but interested in her family." The father, a business manager, was also described as strict, particularly with regard to sex. When

the father became angry, he would withdraw and, after the mother's death, he began to drink heavily. The family lived frugally and the twins considered themselves poor. There was little overt fighting among the siblings. A. felt his twin was intellectually quicker and more apt in school, while B. felt A. more often came up with commonsense solutions to practical problems. Twin A. failed a grade in school and was to be separated from his brother, but A. manipulated the teacher by crying and was promoted along with B. Twin A. was described as the hardest worker in the family.

When the twins were 17, because of their father's excessive drinking they had to leave school to earn a living. A. left first to work as a semiskilled laborer, and he remained in this same job for 34 years. When B. left school he also obtained a blue-collar job but at age 30, during a change of management, he was promoted to a managerial job, which he retained until his death.

Earliest Memories

A.'s earliest memory was of his mother putting him to bed. He also recalled that, at about age seven, he was pushed back into the family's yard to make room for the ambulance that took his mother to the hospital, where she died. There was no affect associated with these memories.

B. had no memories of his mother. His earliest memory was of intervening to protect his twin, who was being chased by some black children. He ran home, got an unloaded rifle, and threatened his brother's adversaries.

A.'s Adult History

A. married at 24 and left the family home. He did not participate in many activities with his wife and avoided arguments with her by quietly walking away. He was devoted to his daily work and to a second, weekend job. A. and B. took lay responsibilities in the same church, but they both left the church after A. was accused of stealing church funds. B. immediately joined and became active in another church. A. stayed away from all church activities for eight years and then joined B.'s new church. A. never again took on church responsibilities.

At the age of 59, two months prior to his admission to Western Psychiatric Institute and Clinic, A. suffered two psychological losses. His wife insisted on moving to a new home, and his daughter moved away from home. He then developed anorexia, impotence, sweating, body tremors, and "butterflies" in his stomach. He was hospitalized and was found to have glycosuria and an abnormal reaction to the glucose tolerance test. Roentgenograms revealed some calcification and tortuosity of his aorta and degenerative spinal osteoarthritic changes. He was discharged with a diagnosis of anxiety reaction and diabetes mellitus. A month later he was rehospitalized for abdominal cramps. He appeared depressed, became belligerent, refused to get out of bed, and said he wanted to be put out of his misery. When A. verbalized delusions about a "fire" and a "devil" in his stomach, he was transferred to Western Psychiatric Institute and Clinic.

During this hospital stay he was demanding, withholding, and overly polite. He was distant from his therapist and refused to discuss any psychological problems. His chronic constipation developed into a fecal impaction. Following its removal by his therapist, the patient's behavior toward her changed dramatically. He immediately kissed her hand and stopped withholding by freely talking about his problems. He entered into a positive therapeutic relationship with his therapist. He gradually recovered and was discharged two months later with the diagnosis of involutional psychotic depression in an obsessive-compulsive personality. He was subsequently treated as an outpatient for three years.

B.'s Adult Life

B. married at age 22 and had a close relationship with his wife and children. He became actively involved in the community and the Boy Scouts. B. had a history of fainting episodes, the first of which occurred in church. Unlike twin A., psychological losses in B.'s life were not accompanied by depression. When he was 50, one of his sons was accidentally killed. Grief-stricken, he lost his voice while ordering flowers for the funeral. When the family's summer home was sold, he began to drink heavily for a short time. That same year, when his oldest son developed marital difficulties, he took his daughter-in-law's side and effectively resolved the conflict. At age 54 he was rewarded for his industriousness at work with an unexpected promotion and a salary increase. He then began to gain weight and, for the first time, became heavier than A. When he was 58 his wife was mistakenly suspected to have cancer. He told no one about this and, following her recovery, he had difficulty recalling her hospitalization.

When he was 60, while putting snow chains on his car tires, B. became cold and clammy and felt pain in his chest, back, and abdomen. When he was examined by his doctor, his blood pressure was 98/58 (it had been 160/100 a month earlier). He was admitted to a hospital. Roentgenograms suggested either a dissecting aneurysm or a dilatation and tortuosity of the aorta. Electrocardiograms indicated coronary insufficiency, but no coronary infarction. Serial electrocardiograms showed gradual but distinct improvement. He was discharged with the diagnosis of coronary insufficiency. Six months later he had an episode of syncope. An electrocardiogram revealed no significant changes. B. was convinced this episode was due to his having drunk wine at dinner and thereafter he avoided drinking wine. Nevertheless, he continued to have blackouts of increasing duration. After one of these he was readmitted to the hospital. An electrocardiogram suggested either coronary insufficiency or myocardial fibrosis with a bundle-branch block. Angiograms revealed an aneurysm of the aortic arch that had dissected to the fourth thoracic vertebra. The patient refused surgery and was discharged. He died three weeks later. Permission for a postmortem examination was not obtained.

In spite of B.'s success in life, he always remained submissive to his less successful twin and had less status in their family.

CLINICAL OBSERVATIONAL DATA

The interactions of the twins during an interview in which both were present, along with two of the authors, illustrate some of the psychodynamics. Whenever A. hesitated or had difficulty responding, B. protectively answered for him. Thus in a potentially threatening situation A. was characteristically helpless (as he was in his earliest memory), whereas B. was characteristically protective of A. (as in B.'s earliest memory). This protectiveness arose not only as an overcompensation for his own anxious, inadequate feelings but also as a reaction formation against B.'s own rivalrous anger toward A.

PSYCHOLOGICAL TEST RESULTS

The results of the psychological tests were consistent with our clinical findings. The twins differed mainly in that A. was more constricted than B. in the degree of his ideational and affective activity. A.'s tight, compulsive defenses limited his potential so that his thinking was stereotyped and he was less reactive than his twin emotionally. B. in contrast was more imaginative and striving. Although A. was ingratiating, self-critical, and depressed, he had little conscious anxiety. B. could think more abstractly and could have longer-term goals and livelier, more enjoyable interactions with the world, but he had more conscious anxiety and conflict.

DISCUSSION

Shields (4), in attempting to analyze the relative importance of genetic and environmental determinants of mental illness in twins raised together and apart, discovered that in individual cases a systematic analysis of the histories showed a relationship between early environment and later findings. The methodological critique of this issue by Rosenthal and Kety (5), although stated in regard to research in schizophrenia, is also applicable to our twin study. Rosenthal stated:

> I think that Dr. Erlenmeyer-Kimling came closest to formulating the issue in a way that is compatible with current knowledge and conducive to developing productive research in the future. She says: "The question to be asked is not: 'What are the relative contributions of heredity and environment' but rather 'What kinds of environmental input trigger manifestations of the disorder in genotypically vulnerable persons, and why are these important, in a psychophysiological sense?' " I myself would have phrased the same point in this way: How do the implicated hereditary and environmental variables interact or coact to make for various kinds of . . . outcomes? The level at which the analysis of interaction would be conducted, i.e., physiological, psychological, or psychophysiological, would be left to the individual investigators, but all such analyses could be informative (5, p. 417).

Our identical twins illustrate the complex interweaving of environmental and genetic factors. Although they were raised in the same environment, they were different in personality and manner of expressing feelings and they displayed a discordance for involutional psychotic depression. Kallmann (6) found that the concordance rate for involutional psychotic depression was 60.9 percent in monozygotic twins and 6.0 percent in dizygotic twins. This shows that although involutional psychotic depression has high hereditability, environmental components are also important in its pathogenesis. Our case suggests some of the environmental factors involved.

Kallmann's studies (6) of manic-depressive and involutional psychoses and Slater's findings (7) with a mixed group of depressives have shown the importance of genetic factors in the etiology of these disorders. Among patients with various neuroses, obsessive patients showed more evidence of genetic predisposition than did hysterical patients (8).

The difference in the twins' birth weights may have influenced the early relationships of the twins within the family. The thinner twin, B., was probably felt to need more food and was given more oral stimulation by his mother. Their busy mother may have felt A. needed less, and she may have given him less gratification.

A.'s two early memories were of being left and rejected by his mother. He was pushed out of the way by the ambulance that took his mother from him, and he was put to sleep by his mother, who thereby left him. A.'s use of isolation of affect as a typical defense is apparent in these early memories, which reflect his apathy and passivity.

B. began using his typical defense—repression—early, in that he had no memory of his mother. His earliest memory was of protecting his brother from injury. This memory may have reduced B.'s guilt for having received more from his mother than did A. Twin B., who got more from his mother, was able to make a positive identification with her and, like her, he became outgoing, aggressive, and phallic. A., who received less and who experienced rejection, became more self-depreciatory, passive, and anal. These early memories support our speculation that birth-weight differences influenced their relationship with, and identification with, their mother.[1]

As a consequence of their different interactions with their mother, the twins developed different modes of defense and different typical reactions to childhood and adult experiences. These differences were prominently shown by the way the twins handled object loss. B. repressed, somatized, and allayed his anxieties with hysterical symptoms, while A. isolated his affect from his ideas and allayed his anxieties by working compulsively or by becoming depressed. In spite of B.'s having been closer to their mother, he had total amnesia for her. Subsequently, B. had amnesia whenever he was confronted with a loss. A. kept busy in order to avoid getting too close to or too involved with people; he felt that if one doesn't have an object, one can't lose it. When A. became

[1] Freud stated that earliest memories are similar to other screen memories or dreams (9). Their manifest content represents the central dynamics of mental and psychosomatic disorders (10, 11).

older, this obsessional defense of isolation failed; when faced with loss, he turned his resultant anger against himself (became depressed). He then clung to his lost object in a circular, ruminatory fantasy or delusion.

Our clinical impressions of the twins were supported by the psychological test data. These studies indicated that twin B. suffered from an anxiety neurosis and from possible hysterical conversion reactions, while twin A. suffered from an obsessive-compulsive neurosis and from depression. Twin A. showed more profound ego constriction than did twin B.

It is known that the compulsive personality is strongly predisposed to involutional psychosis (80 percent of Kielholz' cases [12]). Since one of our twins had a compulsive personality and the other did not, we have evidence to support the notion that the environmental factors that influence the development of an individual's compulsive character traits also predispose him to his later development of an involutional psychotic reaction.

Burlingham (13) pointed out the importance of the interaction of constitutional and maternal influences in determining differences in twins. Hartmann (14), in a review of his earlier study of ten pairs of twins, stated that "differences in orderliness, stubbornness, and stinginess were especially pronounced and most frequently demonstrable." Steinfeld was quoted by Orr (15, p. 287) as stating that "the tendency is for the twins to develop a severe compulsion or anxiety neurosis." These contrasts were also found in the character traits and diagnoses of our twins.

Other studies (15, 16) suggest that the differences in the character traits and diagnoses of our twins might be due to the different ways in which they handled the aggression stemming from their sibling rivalry. In our twins, B. became an aggressive "little devil" who had outbursts of temper, while A. conformed. B.'s guilt for having actively surpassed A. in their competition, first for their mother's attention and later in other spheres, is highlighted both by B.'s earliest memory of protecting his brother and by his assuming an inhibited, submissive attitude whenever he was with A. (16). Bacon (17) found such compliance and defiance in the anginal patients she analyzed.

A. and B. also differed from each other in their physical health. Although both had generalized arteriosclerosis and asymptomatic hypertension, only twin B. had the signs and symptoms of coronary insufficiency and aortic aneurysm. Twin A. had diabetes mellitus, while B. did not have even a latent tendency to develop diabetes mellitus, as far as could be established by laboratory studies.

Many authors have pointed out that patients with coronary disease are subjectively anxious and objectively tense (18, 19); diabetics, by contrast, are apt to be passive or depressive (20, 21). Our data support these correlations.

Hinkle and associates (22) postulated that when diabetics suffer losses, they handle carbohydrates as a starving person would. The losses A. anticipated when he was 59 reactivated the repressed feelings he had experienced as a child when he suffered oral deprivation and when he lost his mother. Could it be that when his psychological defense mechanisms were no longer able to effectively handle his overwhelming oral needs, his body somehow was no longer able to handle his carbohydrate metabolism? Since the twins had identical genetic structures, it is supportive of Hinkle and associates' hypothesis that the disease presented itself only in the more orally deprived twin.

The organic and hereditary bases of myocardial infarction have received a great deal of attention and there has been increasing consideration given to psychological stress and strain factors (23). Studies have been made of focal conflicts (17), character defenses (24), and early life relationships that point to various levels of development, including the age at onset of the infarction (25).

Repression and identification (26, 27) are the important defenses used by myocardial infarction patients to deal with their aggressive impulses. In spite of using these defenses, however, these patients still suffer from a great deal of anxiety. In order to handle this residual anxiety they use other defenses: displacement, avoidance, identification with the aggressor, and overcompensation (18, 24, 27).

The importance of anxiety in B. is also shown in the studies of syncope by Romano and Engel (28). They point out that vasopressor syncope is due to the anxiety of inhibited flight.

B. is also like Kemple's patients (29), who had difficulty expressing feelings and who developed vascular disease. B.'s amnesia for his mother, his early memory of protecting his brother, and his adult use of avoidance and hysterical somatization when under stress all point to his difficulty in handling aggressive feelings.

Twin A., who isolated his feelings, had general arteriosclerosis and diabetes mellitus but did not develop symptomatic cardiovascular disease. On the other hand, twin B., who, in spite of his use of repression and avoidance as defenses, was often consciously anxious, did develop cardiovascular symptoms. Some researchers (26, 27) have demonstrated this use of avoidance and repression in the patients they found to be prone to coronary disease.

CONCLUSIONS

We have studied a pair of monozygotic twins who, late in life, became discordant for mental and physical disorders. Differences in the twins' birth weights, early histories, earliest memories, and reactions to the loss of their mother when they were seven years old suggest that in their early interaction with their environment they developed different modes of adaptation, which subsequently became internalized as different defensive and characterological patterns. Twin A. isolated his feelings, while twin B. used avoidance defenses and repression. Thus the older twin, A., became an obsessional character, while the younger twin, B., came to suffer from an anx-

iety neurosis in a hysterical character. As is consistent with the findings of others, the twin with the obsessional character, who used isolation as a defense, developed diabetes mellitus and involutional depression, whereas the twin with the hysterical character, who suffered from anxiety and used repression as a defense, developed coronary insufficiency and an aortic aneurysm.

Thus in these monozygotic twins, both of whom were equally genetically predisposed to diseases, we have documented some of the specific environmentally determined psychodynamic influences that may have made them discordant. Confirmatory studies are needed.

Our investigation confirms the value both of the single twin-pair study and of the use of earliest memories in clinical investigation. There is a need for further studies of discordances in individual pairs of twins who suffer from diseases that are partially genetically determined.

Levoamphetamine and Dextroamphetamine: Differential Effect on Aggression and Hyperkinesis in Children and Dogs

BY L. EUGENE ARNOLD, M.D., VLADIMIR KIRILCUK, M.D., PH.D., SAMUEL A. CORSON, PH.D., AND ELIZABETH O'L. CORSON, M.S.

In laboratory experiments with hyperkinetic, untrainable dogs and in a comparison of levoamphetamine, dextroamphetamine, and placebo in children, levoamphetamine and dextroamphetamine were found to be approximately equal in calming an aggressive, hostile dog and in benefiting "unsocialized-aggressive" children; dextroamphetamine was more effective than levoamphetamine in calming "nervousness" and hyperactivity in dogs and in overanxious-hyperkinetic children. These data suggest that in the hyperkinetic syndrome, aggression and hostility may be benefited equally by levoamphetamine or dextroamphetamine via a dopaminergic mechanism, while anxiety and overactivity may be benefited significantly only by the dextro isomer via a norepinephrinergic mechanism.

THE PLIGHT OF children with behavior and learning problems that often respond to stimulants by "paradoxical" calming has become well known under such names as "hyperkinetic syndrome," "minimal brain dysfunction," and "minimal brain damage." These and other grammatically singular appellations are bandied as if we believed these problems represented a single, homogeneous clinical entity (like pneumococcal pneumonia) that would uniformly respond to a prescribed treatment, if only we could find the treatment. However, those familiar with the syndrome readily admit its diversity of clinical pictures, probable diversity of etiology and pathogenesis, and even diversity of response to the highly touted stimulant therapy.

At least two authors have recently attempted to clean up this diagnostic cesspool. Fish (1) has proposed criteria by which children who may respond favorably to stimulants could be assigned to one of three diagnostic categories: 308.0—hyperkinetic reaction (with immaturity, inadequacy, lability, and poor organization); 308.2—overanxious reaction ("nervousness" and possible overactivity with subjective distress, otherwise well-organized behavior); and 308.4—unsocialized-aggressive reaction (aggressiveness and hostility with denial of feelings and personal responsibility, otherwise well-patterned behavior). These categories are reminiscent of Wender's "classical hyperactive," "neurotic," and "sociopathic" subsyndromes (2).

One of the puzzling things about the hyperkinetic syndrome that raises serious questions about its being a homogeneous diagnostic entity is the individual variation in response to stimulants. It has long been known (3, 4) that sometimes dextroamphetamine helps a hyperkinetic child more than the racemic (dl) mixture does, and sometimes vice versa. In addition, some children are helped by methylphenidate (Ritalin) but not by amphetamine, and vice versa. Furthermore, while the majority of such children are helped by stimulants, a small percentage are actually made worse. The uncertainty concerning the practical clinical use of drugs for these children is underscored by recent attempts to introduce some prognostic guidelines. Barcai (5) has proposed a finger twitch test. Yoss and Moyer (6) have found that 25 percent of hyperkinetic and underachieving children have a narcoleptic-like electronic pupillogram that changes favorably with behavioral improvement on amphetamine. Knopp and associates (7) have found a correlation of approximately 0.6 ($p<.01$) between behavioral response to dextroamphetamine and changes in the extent of pupillary light reaction before and one-half hour after a test dose.

The question naturally arises whether the differential drug effects may be correlated with the different diagnostic categories proposed by Fish (1) and Wender (2). Clinical pharmacological separation of the aggressive and "nervous" components of the hyperkinetic syndrome seems to be supported by data from pilot psychopharmacologic experiments with hyperkinetic, untrainable dogs in the Laboratory of Cerebrovisceral Physiology of the Department of Psychiatry, Ohio State University in Columbus.

The authors are with Ohio State University, Columbus, Ohio 43210, where Dr. Arnold is Assistant Professor of Psychiatry and Pediatrics, Dr. Kirilcuk and Ms. Corson are Research Associates in Psychiatry, and Dr. Corson is Professor of Psychiatry (Physiology) and Biophysics.

The dog studies were supported in part by Public Health Service grants MH-12089 and MH-18098 from the National Institute of Mental Health and by Ohio State University College of Medicine.

The authors wish to thank Marcia Norman and James Scheib for their assistance in collating data and Donald Smeltzer, M.A., for his statistical consultation.

DOG EXPERIMENTS

Method and Results

The four hyperkinetic, untrainable dogs used in this pilot study were previously reported on by Corson and associates (8,9). Most of the dogs were merely hyperkinetic, not particularly vicious. One of them, however, a cocker-beagle, was both hyperkinetic and aggressively hostile, providing a neat animal model for the constellation of symptoms seen in some aggressive hyperkinetic children.

While aggressive behavior could be easily observed, even in the dog's home cage or kennel, the hyperkinetic traits could be best observed when a dog was placed on a Pavlovian stand, mildly restrained, and left alone in a soundproof chamber, as described by the Corsons elsewhere (10). Therefore, experiments were conducted in both settings.

In cage experiments the aggressive hyperkinetic dog was given either l- or d-amphetamine (10 mg. orally) on different occasions. Each time, amphetamines had a very pronounced effect: By approximately one hour the ordinarily vicious dog completely lost his aggressiveness. It was possible to take him out of the cage, walk him, pet him, and feed him a treat without danger of the experimenter's being bitten.

Although both isomers were equally effective in suppressing aggression, the duration of effect was different: While d-amphetamine kept the dog quiet seven hours after administration, l-amphetamine lasted only about half as long.

On the Pavlovian stand, "normal" dogs, after a few unsuccessful tries to escape, eventually give up fighting and tolerate the restraints. By contrast, "hyperkinetic" dogs immediately start thrashing, chewing equipment within reach, and trying to free themselves. This behavior would go on for indefinite numbers of experiments; they simply would not adapt to the experimental situation.

Pavlovian-stand experiments in which both isomers were used were carried out on four hyperkinetic dogs, including the vicious one. The dosages varied from 2.5 to 40 mg. (.25 to 4.0 mg./kg.). For each dog, elimination of all signs of hyperkinetic behavior required three to four times as much levoamphetamine as dextroamphetamine. The vicious dog, for example, required 40 mg. of levoamphetamine to eliminate hyperkinesis as effectively as 10 mg. of dextroamphetamine did, even though his aggression and hostility were eliminated by 10 mg. of either isomer.

This differential effect on hyperactivity paralleled the differential effect on appetite. The three dogs who showed anorexia did so with 1.0 mg./kg. of dextroamphetamine but required about three times that amount of levoamphetamine to produce anorexia. Unfortunately, dextroamphetamine had been tried before levoamphetamine in these exploratory experiments, so that tolerance cannot be ruled out as a source of the apparent difference in anorexogenic potency.

Conclusions

Thus, from pilot animal experiments in standardized laboratory settings, we have data suggesting that in hyperkinetic organisms: 1) levoamphetamine has a shorter duration of action than dextroamphetamine; 2) during the duration of maximal effect, levoamphetamine and dextroamphetamine seem to be approximately equal in their aggression-taming potency, but dextroamphetamine is three to four times as potent in calming "nervousness" and in producing anorexic effects; and 3) therefore, the beneficial effects of amphetamine on aggression and "nervousness" may operate through different biochemical mechanisms.

CHILDREN

Method and Design

Encouraged by these findings in laboratory dogs, we returned to the raw data of a previously reported nine-week double-blind crossover comparison of levoamphetamine, dextroamphetamine, and placebo (11) that demonstrated the efficacy of levoamphetamine in hyperkinetic children. This study had only 11 subjects, but it offered reliable, quantitative, independent ratings by psychiatrists, teachers, and parents. Without being consciously aware of how each child fared comparatively on the dextroamphetamine and levoamphetamine ratings,

we assigned each of the children to one of the three diagnostic categories advocated by Fish (1). This resulted in five diagnoses of unsocialized-aggressive reaction (308.4), four diagnoses of overanxious reaction (308.2), and two diagnoses of hyperkinetic reaction (308.0).[1]

Because these last two groups were so small and because we were mainly interested in aggression as opposed to other manifestations of minimal brain dysfunction, we lumped those with overanxious reaction and those with hyperkinetic reaction together as the "overanxious-hyperkinetic" group for statistical comparisons on the three sets of ratings.

Results

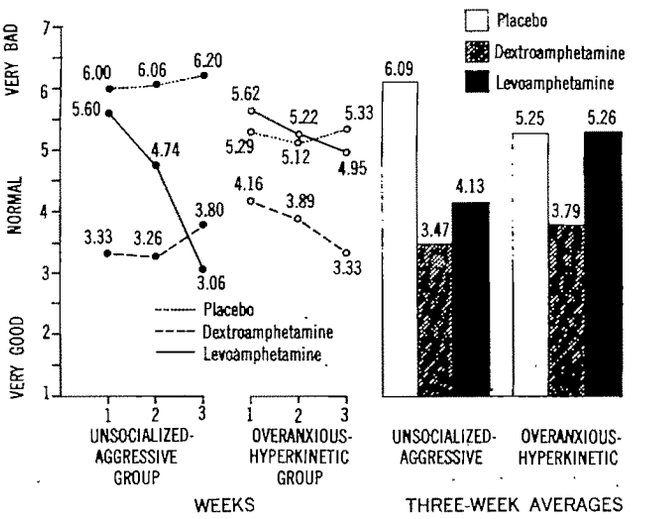

Figure 1 shows the psychiatrists' ratings for the two groups; they are mainly based on weekly parental quantification of target symptoms. The three independent raters had an overall interrater reliability coefficient of 0.7734. Note that for the unsocialized-aggressive group levoamphetamine was rated as being almost as good as dextroamphetamine (difference not significant), and both of these active drugs were significantly better than placebo. In contrast, for the overanxious-hyperkinetic group the levoamphetamine was no better than placebo, even though dextroamphetamine was significantly better (see table 1).

The same pattern emerged when the two groups were compared on the teachers' behavior rating scale (figure 2). Here we find that in the unsocialized-aggressive group levoamphetamine was actually rated slightly better than dextroamphetamine (difference not significant). Both active drugs were significantly better than placebo. Again we find that in the overanxious-hyperkinetic group levoamphetamine is rated as not significantly better than placebo, and dextroamphetamine as significantly better than either placebo or levoamphetamine (table 1).

The parents' behavior checklist (figure 2) does not at first seem to show the same pattern. However, if we attend only to the differences that are statistically significant ($p<.05$ level), they do partially support the same pattern as the psychiatrists' and teachers' ratings. In the unsocialized-aggressive group both active drugs were rated as significantly better than placebo and not significantly different from each other. All differences for the overanxious-hyperkinetic group were not significant (see the results of comparison by one-tailed paired t test in table 1).

FIGURE 1

Comparison of Two Diagnostic Groups on Psychiatrists' Ratings of Drug Effect with Placebo, Dextroamphetamine, and Levoamphetamine*

* 1 = best possible rating; 7 = worst possible rating.

Individual factor scores for aggression, hyperactivity, and daydreaming-inattention on the pooled teachers' symptom ratings (11) likewise only partially showed the same pattern. The aggression factor showed comparable isomeric efficacy, as did the aggressive dog and the unsocialized-aggressive group. Further, the daydreaming-inattention factor showed a statistical gap in isomeric efficacy, as did the hyperkinetic dogs and the overanxious-hyperkinetic group. However, the hyperactivity factor showed comparable efficacy, a flaw in the pattern seen in the rest of the data.

To rule out dosage variation as a source of the differences in efficacy, the average number of tablets given per day for each drug condition was tabulated by diagnosis (see table 2). The range of dosage is rather narrow, and what variation there is tends to dramatize the observed differences rather than question them. The clinicians had been instructed to optimize the dosage on each drug condition. Therefore an ineffective drug would tend to be given in higher dosages, as shown by the placebo doses. For the overanxious-hyperkinetic group, where levoamphetamine seemed ineffective, the drug was used in a dosage comparable to placebo, while dextroamphetamine, which was significantly more beneficial, was used in a much lower dose. For the unsocialized-aggressive group, where levoamphetamine seemed as beneficial as dextroamphetamine, levoamphetamine was used in lower doses.

[1] The unsocialized-aggressive group included two brothers with a chronic history of frequent serious fighting, stealing, and lying; a boy who had been expelled from two schools for misbehavior and had set a $1,200 fire; and two other boys who were repeatedly suspended from school for fighting and other aggressive behavior and whose mothers asked for tranquilizers for themselves by the end of the boys' second week on placebo. One of these boys had thrown furniture at other children in the classroom. Both had a tendency to blame everyone else for their trouble; this sometimes verged on paranoia. Their parents seemed less adequate than those of the other two groups.

The overanxious group was characterized by likability, subjective distress, anxiety, some insight, at least one loving, stable parent, and generally higher intelligence than the other two groups.

The classical hyperkinetic group were also characterized by likability and at least one stable, loving parent. One of the children in this group was a postmeningitic kindergartener. Another carried the only diagnosis of mental retardation (borderline) in the study. His mother was concerned about his occasional bullying of smaller children, but this was not the most prominent manifestation of his problems, and the school did not complain about it. Because of his general disorganization and inadequacy, it seemed most appropriate to place him in this group rather than in the unsocialized-aggressive group.

TABLE 2

Comparison of Two Diagnostic Groups on the Average Number of Tablets Used a Day for Each Drug Condition

Medication	Number of Tablets a Day	
	Unsocialized-Aggressive Group	Overanxious-Hyperkinetic Group
Placebo	6.9	7.0
Dextroamphetamine*	6.5	5.7
Levoamphetamine*	5.7	6.9

* One tablet = 5 mg. of amphetamine sulfate.

DISCUSSION

The teachers' ratings and the psychiatrists' ratings of weekly parental assessments of target symptoms in a double-blind crossover study on hyperkinetic children, as well as careful laboratory observations on a hyperkinetic aggressive dog, all suggest that aggressive, hostile behavior may be a distinct (if not separable) part of the hyperkinetic syndrome. It seems to be helped by levoamphetamine as much as by dextroamphetamine, in contrast to anxiety and overactivity, which appear to be helped significantly more by dextroamphetamine. The observations made on laboratory dogs demonstrate this contrast in the same organism; the data from the children's study show it from patient to patient. While the nonaggressive children who were merely hyperactive benefited significantly only from dextroamphetamine, the most aggressive children enjoyed approximately equal overall improvement when taking either levoamphetamine or dextroamphetamine.

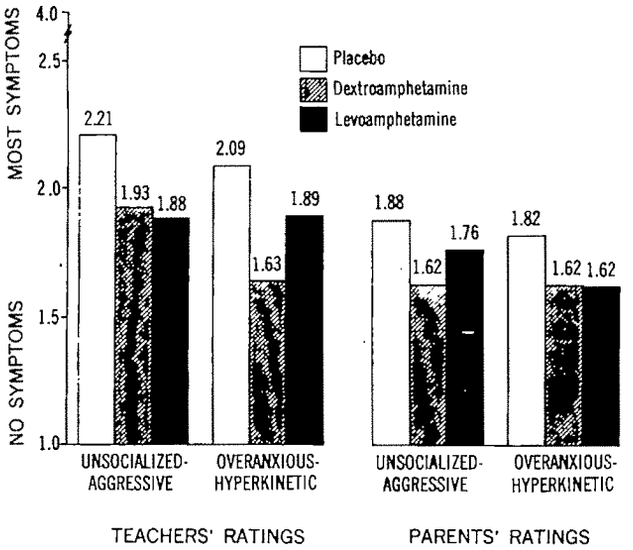
With regard to the latter, levoamphetamine, insofar as it has fewer "central side effects" than dextroamphetamine, may eventually become the drug of choice for the aggressive, hostile subgroup of hyperkinetic children who would be diagnosed by Fish's criteria as having "unsocialized aggressive reaction" (308.4). However, this is far from established by the data presented here, especially in view of: 1) the small numbers of children in the clinical study, 2) the retrospective nature of the assignment to diagnostic categories, 3) the failure of parents' ratings and pooled teachers' rating factors to confirm all the findings on psychiatrists' ratings and teachers' rating totals, and 4) the preliminary nature of the dog experiments. Further investigations on both animals and children are obviously needed.

Whether levoamphetamine (and dextroamphetamine) may be useful in treating other kinds of aggression remains unclear at this point. Goldman, Lindner, and Dinitz at Ohio State University are initiating a double-blind comparison of placebo, levoamphetamine, dextroamphetamine, and imipramine in sociopathic convicts that may provide some information along this line. However, it may be argued that the aggression seen in sociopaths is not really a different kind; there is a suspicion that at least some sociopaths are hyperkinetic children grown up.

The differential response to levoamphetamine, if upheld by further investigations, would tend to validate Fish's proposed diagnostic groupings for children with behavior disorders. Here, for the first time, we may have the beginnings of a diagnosis-treatment situation analogous to diagnosing pneumococcal pneumonia and treating it with penicillin rather than diagnosing Hemophilus influenzae pneumonia and treating it with ampicillin. Obviously, there remain many unanswered questions, some of which follow.

1. It would be difficult to guess from the currently available data whether or not the "classical hyperkinetic" subgroup of hyperkinetic children should be lumped together with the "overanxious" group with regard to drug response, whether it would be more like the "unsocialized-aggressive" group, or whether it would be different from either.

2. The place of learning disabilities in this scheme would need clarification. It is now known that some children who show primarily a learning disability without obvious behavior problems can also benefit from "stimulant" medication (12). Would such children in their drug response more closely parallel the unsocialized-aggressive group or the overanxious-hyperkinetic group, or would they constitute yet another group?



3. The possibility of synergism between the optical isomers of amphetamine remains unexplored. The biochemical literature scarcely recognizes the possibility except for isolated, brief speculation (13). In the clinical literature the occasional superiority of racemic (dl) amphetamine over pure dextroamphetamine is reported without explanation (3, 4). It could result from either synergism or merely an additive effect since the racemic mixture is usually given in higher doses than pure dextroamphetamine. Two clinical observations more strongly suggest a possible synergism:

A. Immediately upon completion of the double-blind, triple crossover comparison, six of the 11 children were given racemic amphetamine in the same total daily dose as an interim medication until the code was broken in order to determine which of the isomers they had fared best on. Out of curiosity, the clinician involved (L.E.A.) did not tell the teachers that the study had ended and had them fill out an additional rating scale for the child's behavior the first week he was on racemic amphetamine. Five of the parents also cooperated by filling out an additional parent's rating. This "piggyback" experiment was thus blind only in regard to the teachers' ratings. The racemic amphetamine was reported to be the most effective of all four drug conditions by both teachers' and parents' checklists for two of the children, by the teachers' checklist alone for one child, and by the parents' checklist alone for one child.

B. The other clinician in our original study (Keith R. McCloskey [11]) has since independently reported that he has found children who respond favorably to various ratios of dextro- and levoamphetamine but not to any other combination or to either isomer alone.

FIGURE 2

Teachers' and Parents' Blind Ratings of Two Diagnostic Groups' on Placebo, Dextroamphetamine, and Levoamphetamine*

* 1 = no symptoms; 4 = most symptomatic.

Though both of these data are open to many criticisms, they do suggest that the potency relationships of the optical isomers of amphetamine may be more complex than has been previously realized and need to be further investigated both for their practical clinical applications and for their value in elucidating basic neurochemical phenomena.

In a previous paper (11), the reasons were detailed for suspecting that, insofar as the levo isomer's efficacy matches that of the dextro isomer, amphetamine may help hyperkinetic children via a dopaminergic mechanism, whereas a wide disparity between the efficacies of the two isomers would suggest a norepinephrinergic mechanism. Briefly, Snyder and associates (13) showed that dextroamphetamine is ten times as potent as levoamphetamine in inhibiting catecholamine uptake by norepinephrinergic terminals and in eliciting locomotor activity in rats (believed to be norepinephrinergic) but that it is of comparable potency in inhibiting uptake by dopamine neurons or in eliciting stereotyped compulsive gnawing in rats, believed to be a dopaminergic-mediated syndrome.

Further suggestive evidence for levoamphetamine's dopaminergic mode of action may lie in its apparent slow attainment of efficacy compared with dextroamphetamine on psychiatrists' ratings (see figure 1). Such slow-starting efficacy in hyperkinetic children has also been reported (14) for magnesium pemoline, believed to be strongly dopaminergic (15). This slow onset of action also recalls that of the major tranquilizers, whose antipsychotic properties are suspected to be inextricably linked to their typical extrapyramidal side effects (which are probably antidopaminergic). However, no conclusions should be drawn on the basis of these scanty data, especially since the temporal pattern seen on psychiatrists' ratings does not emerge on teachers' or parents' ratings.

Supporting a dopaminergic mediation of aggression control, McKenzie (16) reported that apomorphine, believed to be a specific dopaminergic agonist, induces spontaneous aggression in male rats. Although this would seem to imply that dopaminergic drugs should exacerbate aggressive behavior, we must remember that some drugs have a paradoxical, reverse effect on some hyperkinetic children. At least, this finding supports the suspicion that dopaminergic receptors are "where the action is" for aggressive behavior.

In this light the data presented here suggest the following hypothesis for further testing: that the unsocialized-aggressive subgroup of hyperkinetic children may benefit equally from either dextroamphetamine or levoamphetamine via a dopaminergic mechanism, in contrast to the overanxious and hyperkinetic children who are helped significantly by only dextroamphetamine via a norepinephrinergic mechanism. This hypothesis is far from established, but there does seem to be enough suggestive evidence to warrant further investigations along these lines.

PRELIMINARY ANNUAL MEETING PROGRAM

The March issue of the *Journal* will include the preliminary program for the 126th annual meeting of the Association, to be held in Honolulu, Hawaii, May 7–11.

No-Suicide Decisions: Patient Monitoring of Suicidal Risk

BY ROBERT C. DRYE, M.D., ROBERT L. GOULDING, M.D., AND MARY E. GOULDING, M.S.W.

The authors describe a simple, rapid method by which patients with any suicidal ideas can determine for themselves and the evaluator what risk actually exists. The patient states how long he is willing to stay alive, without qualification, in the form of a decision rather than a promise or agreement with the evaluator. This method has been used successfully in various settings and with seriously ill patients.

IN THIS PAPER we describe a method to be used by anyone evaluating a patient as a suicidal risk; the method enables the evaluator to make the following judgments: Is suicide a risk at all for this patient? If it is a risk, to what degree and for how long can the patient be trusted not to kill himself?

This second judgment is important at every stage of treatment in any setting, since on the basis of this judgment the evaluator or therapist (and the patient) will decide on outpatient versus hospital care and may decide to use the milieu, drugs, shock treatment, or psychotherapy in very different ways. (We have not used shock treatment with any patient evaluated under our method.)

Up to the present time no precise technique of measuring suicidal risk has been available to the evaluator. Various methods have been suggested for making the first judgment, including demographic and sociologic (1, 2), psychodynamic, clinical historical, and interpersonal (3–5), and biochemical (6) criteria. Longitudinal studies of major mental illnesses have indicated higher risk for suicide among recovering depressed and schizophrenic patients (7). A classification of suicidal styles (8) has also been suggested. Shein and Stone (9) have emphasized the importance of asking the patient directly about any suicidal thoughts—something that is not done often enough.

We believe that these approaches, which sometimes include rating scales and checklists, are useful in three ways. They increase the probability that the evaluator will make some judgment about suicide, they help him in deciding that some risk does exist, and they may suggest preventive techniques at a large group or community level. However, they do not help the evaluator enough with the second decision. On at least one scale (1), 35 percent of a group of high-risk patients actually committed suicide within a one-year follow-up (major attempts included). Such a high risk means that the evaluator must either excessively hospitalize the patient or trust him not to commit suicide, while not knowing what degree of risk exists for a particular patient.

Evaluative comments such as "points toward" are not precise enough in describing suicidal risk. They are likely to produce great anxiety in the patient, the evaluator, and concerned others. The psychiatrist, who may be appealed to by a less experienced or less professional evaluator, does not necessarily have more confidence. Aphorisms such as "You don't get paid for being smart, you get paid for sitting with this kind of patient" or "You won't be a real psychiatrist until you've lost one," which we remember from our training days, are neither comfortable nor useful with the individual patient. Many suicidal patients invite the evaluator to overestimate or underestimate the risk by dramatic or demanding behavior.

We believe that our method offers substantial advantages both for accuracy in planning with the patient and in removing the burden on the evaluator. We share the evaluation task with the patient. Since he is the one who is making the decision to kill himself or not, he has the best data—not only on how intense his urge is, but on how strong his controls are. Specifically, the patient can tell the evaluator how long, and under what conditions, he trusts himself to exercise control over his impulses. This approach developed out of our belief that the only therapeutic contracts likely to lead to change are those developed by the patient himself, for which he will assume responsibility. Particular therapeutic schools that emphasize this approach and that have influenced us include psychoanalysis, transactional analysis, and gestalt therapy. The only exceptions to this approach would be those patients who have organically impaired cerebral function. Psychotic patients who are willing to use this method can do so. The method will also work in any setting, including over the telephone, although there the evaluator's lack of awareness of the patient's body language may hinder evaluation.

METHOD

To begin with we have a high index of suspicion that suicidal fantasies may be present in any depressed patient

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Drye is Lecturer in Psychiatry, Stanford University School of Medicine, Palo Alto, Calif. He is also on the staff of the Western Institute for Group and Family Therapy, Watsonville, Calif., where Dr. Goulding is Director and Ms. Goulding is Co-Director. Dr. Drye's address is Box 6116, Suite 150, 4th and Junipero, Carmel, Calif. 93921.

and in many patients with hypertension, a history of coronary occlusion, and other life-threatening illnesses. In addition to the indicators alluded to previously, we particularly investigate inappropriate laughter occurring during discussions of bad predictions (such as divorce, business failure, or illness). As part of history taking we often ask the question, "If things go badly for you, what will your life be like a year from now?" These are items developed from a checklist by Steiner (10) and, more recently, by McCormick (11) to put patients in touch with the many important predictions they make for themselves, often out of awareness. If any suicidal or self-destructive fantasies appear they are carefully investigated with the patient. These include fantasies of accidents, abuse of food, alcohol, or drugs, or exhausting work habits.

As soon as the evaluator believes that the patient is aware of his fantasies, he asks the patient to make this statement: "No matter what happens, I will not kill myself, accidently or on purpose, at any time" and to report his internal responses to this statement. If the patient reports a feeling of confidence in this statement, with no direct or indirect qualifications and with no incongruous voice tones or body motions, the evaluator may dismiss suicide as a management problem. In addition, the patient will often express considerable relief, since suicidal fantasies can be quite frightening. Finally, the settling of these fantasies frees patients who are not actively suicidal from ruminations they have been using to delay dealing with other reality or interpersonal or intrapsychic problems, since "If I'm going to commit suicide one of these days anyhow, why bother?"

The patient for whom suicide is an important issue will either object to or qualify the statement about suicide. The various qualifications will be described shortly; objections are classified as "I can't" or "I won't." A patient who will not make the statement is assumed to be suicidal, and he is advised that his choice is to make the statement with whatever qualifications he wishes, or have us make arrangements for his security. If he says "I can't," we ask him to say "I won't" and to report whether this is closer to what he is feeling. (Whether or not he feels he can control his suicidal impulses, he is obviously *able* to make such a statement.) If he changes to "I won't," we offer the choice between a statement and security arrangements, as before. At this point the evaluator can classify any patient as representing no risk, a very high risk, or a qualified risk. The qualifications are then considered under three major headings: No matter what; I won't kill myself; and Until. Dispositions for no-risk and very-high-risk patients are made as soon as the suicide issue has been settled for them.

Qualifications

Before considering the specific qualifications, how do we understand qualification? Anyone who is considering suicide finds it useful, if only in fantasy. In the present it may represent relief, revenge, and so forth. In the past it may represent a solution acceptable or even welcomed by significant others (12). Giving up the suicidal fantasy or behavior is experienced by the patient as a loss of a present problem-solving technique and/or fantasy gratifications. Qualifications enable the patient to psychologically avoid the loss since he retains his basic position of "I will only stay alive if " and has not made a decision not to kill himself. We use the term decision (or redecision [12]) because only the patient can act. If the statement is not experienced by the patient as a decision, we do not trust it. Since it is his decision, all qualifications involving the behavior of someone else, including the evaluator, are not accepted.

Until. The easiest qualification is time. While any time shorter than never allows for suicidal fantasy, we can plan very differently with a six-month safety margin than we can with an hour. A six-month span offers time for detailed therapeutic work on whatever reality or personal problem emerges elsewhere in the patient's qualifications. One hour allows the patient to make short moves unescorted, such as from our office to a nearby psychiatric ward. Furthermore, as the patient experiences even brief mastery of his suicidal impulses and begins to see possible solutions to his dilemma, he will usually fairly quickly extend his time qualification. It is our practice to ask for the longest time the patient will readily agree to; the shortest we will accept is that which allows the patient to see us or another reliable person. All decisions are renewed before their time expiration, regardless of any apparent clinical improvement in the patient.

I will not kill myself. The focus in dealing with patients using this qualification is on the first two words. We emphasize that a decision is possible, but only the patient decides. For instance, "Nothing will happen" is a much feebler statement than "I won't do anything." "I'll try," "I'd like to," and "I'll probably" are all countered with "But will you?" "I promise" is also shaky; like the statement in the previous sentence, it often has the flavor of a child being asked to do something by a parent that the child regards as too unpleasant or difficult. The child's response is intended to get the parent to stop asking and not as a commitment.

Evaluators who accept an "I'll try" statement are making the same mistake as parents who accept trying instead of doing without recognizing the difference. The patient's statement "I promise" provides many opportunities for setting up the evaluator as someone who is supposed to be disappointed, and the patient sets himself up for rebellion, shame, and guilt. Any decision he makes is not an agreement with the evaluator, but a self-contained choice. (This, of course, does not psychologically diminish the potential importance of the evaluator.) The "I" may be supported by shortening the time span, or the evaluator may choose to do some brief therapy around the statement "It sure seems important for you to be scared [angry, impulsive, confused]," reminding the patient that he has control over himself there, too.

No matter what. This qualification allows the patient to shift responsibility for a suicidal act to someone or something else. (It is often also, of course, related to important therapeutic issues, once suicide has been tem-

porarily removed from the foreground.) This type of qualification may be as vague as the philosophy "People should be allowed to dispose of their own lives their own way" or as immediate as "I don't like what you [evaluator] are doing." Common statements include "As long as my husband [wife, child, lover] does [or doesn't]," "Unless I get drunk [tired, upset]," "Unless work [school, marriage] goes better," or their only apparently positive variations, "I'm too attached to my children" or "I'm such a coward." The whole purpose of an unqualified statement as a decision is to get the patient past just these external sources of trouble. Even if these are dropped after a time limitation, we feed these qualifications back to the patient so he can hear how he uses others to increase bad possibilities for himself.

We don't argue with philosophical patients; unless they are willing to make a decision, they are going to be supervised like anyone else. One of us (R.L.G.) often asks such patients, "Would you be willing to consider that you are not the one who originally thought of knocking yourself off, and that it was a choice you made many years ago, which only seems to be your free choice now?" If they are willing to consider this possibility, we may do some work around their original decision (12) and then ask again for a decision now. The patient is in charge of how drunk or upset he is going to be and what options he will allow himself in his important life situations; the details of this will be central in therapy.

The evaluator also does not take responsibility. For instance, if the evaluator will realistically not be available for frequent telephone calls, this is included in the decision, i.e., "Even if I can't get hold of you." In practice, the evaluator will get occasional telephone calls, but many fewer than if he follows the common recommendations to tell the suicidal patient "I'm always available." (If the patient wants to call and we are available, we don't deny it.)

We previously noted that we ask the patient to state "I will not kill myself, accidentally or on purpose, at any time." "Accidentally" is intended to deal with those patients who are unaware that they are in a suicidal position and who have had automobile accidents or skiing accidents, are parachutists, or in some other way are seriously endangering their lives by their activities. Not everyone who skis or parachutes is in a suicidal position, of course, but everyone who doesn't fasten his seat belt, drives dangerously, or hurts himself skiing may be, and the truth may be obvious once the question is put to the patient. The same may be true of patients with hypertension or a history of coronary occlusions, who may become aware of the ways in which they are endangering their lives once they have made a full statement.

RESULTS

We have used this method with patients of all diagnostic categories in such diverse settings as Monterey County, Calif., and metropolitan Chicago, in hospitals, clinics, private offices, and community agencies, and in two- or three-day marathons with out-of-town patients both in California and throughout the country. Over the last five years approximately 600 patients have made no-suicide decisions. Our fatality rate with patients during a no-suicide time span is zero. (Two patients known to us did commit suicide; they had refused to make a decision, were hospitalized, changed therapists, and were not under any supervision at the time of suicide.) Furthermore, we are active clinical teachers and (particularly R.L.G. and M.E.G.) have presented this method to many mental health professionals locally and nationally at major meetings and teaching centers.

To date we have not heard of a failure when our criteria have been strictly applied. We have sent questionnaires to all our trainees regarding their results. Thus far 31 therapists have reported on 609 patients, 266 of whom they considered seriously suicidal. One patient killed herself outside the time period. Three patients died or made serious suicidal attempts within the time period. One patient who was assumed to have organic brain disease (epilepsy) made a serious attempt. Another patient died in an automobile accident. State police said she was driving at normal speeds and wrecked her car while avoiding a poorly marked mud slide. The third patient took a fatal overdose of sleeping pills while drinking heavily. The 31 therapists we surveyed reported 20 suicides or serious attempts in their practice where they had not used this method, usually before they were aware of it.

CASE REPORT

Case 1. A 22-year-old man was referred by a Veterans Administration hospital after three hospitalizations in the past year, two after serious suicide attempts with barbiturates. The patient stated on the first visit that he felt better, but that within a few weeks he expected to begin drinking, with progressive withdrawal and increasing suicidal fantasies. He made a no-suicide decision for a week. Over the next three weeks he became progressively more suicidal and suddenly left a session without making a decision. One of us (R.C.D.), the patient's therapist, called the police; the patient returned after learning of this and gave the therapist a knife he had been carrying. He made a new one-week decision, but after another week again felt very depressed and refused to make a decision. He immediately went home and threatened a younger brother, surrendering to the police when they were called. After a brief hospitalization at the local emergency ward he again resumed this pattern. After three weeks he requested rehospitalization at the VA. While there, in consultation with the VA staff, he was advised that we would not reaccept him as a patient without a six-month no-suicide decision. He made this decision December 15, despite the fact that his mother refused to have him live at home again.

He attended group therapy weekly and shifted from scoffing at himself for his decision ("just waiting to backslide") to a somewhat moralistic lecturing to others to stop feeling sorry for themselves. He first went on a diet and then stopped drinking, stopped smoking, managed to deal with several disappointments with friends by brief withdrawals, began a successful house-painting business, and otherwise described himself as being in the best condition in years. Later, in May, he suddenly

skipped two group sessions, and his landlady, who knew the therapist socially, called to express concern about his withdrawal and sleeping late. The therapist wrote him a brief note asking him to come in, particularly since the therapist wanted to renew the patient's contract, which he thought ran out about June 30. The patient came to the next group session on June 22 and described a very difficult period he had experienced both immediately before his contract expired June 15 and afterward. He had suddenly felt very depressed despite his successes and had some suicidal fantasies, which were strong but not as intense as those he had had the previous fall. After some expression of concern from the therapists and group members, and recognition of both his distress and success in mastering these fantasies, he readily made another six-month decision. He refused to make a longer one, saying, "I still need an escape somehow."

He then attended group sessions irregularly until last September 1, when he became concerned about a moderate return to drinking and social pessimism (essentially that he would not be able to get a girl friend). His no-suicide contract was to last until January, and he spent little time thinking about it, other than being aware that he might use some of his current difficulties to work himself into a mood where he would be reluctant to extend his decision. This patient comes from a family in which a number of serious suicide attempts have been made, and his father talked of or threatened suicide frequently when the patient was a boy. Dropping the idea of suicide completely will therefore mean a considerable personal change for this man, but the contrast between his behavior on six-month decisions and short decisions is very striking.

DISCUSSION

This combined diagnostic and management technique has very high effectiveness in reducing patient and staff anxiety and complete effectiveness in evaluating suicide risk. It is suitable for use by inexperienced nonprofessionals as well as by experienced professionals. There are two situations where its use requires considerable flexibility. One of these is long-term therapy, where the method itself becomes a major issue in the relationship and needs to be dealt with as a relationship issue in addition to its immediate practical value. The other situation is with patients who, even more than the man cited here, have made suicide the central theme of their lives. An adolescent and a 35-year-old divorcée, for instance, both spent most of every day working away from or toward suicide. As of this writing the adolescent, who has never hurt herself seriously, either on or off a decision, has withdrawn from treatment for six months, with no serious attempts; the divorcée has been briefly hospitalized several times. Both patients occasionally called the therapist or other help givers at times when they doubted that they could continue on a particular decision. With both of these patients, the emptiness of their lives without the excitement surrounding suicide and the importance of the therapist's reactions to the frequent decisions are important issues. Finally, this method is not safe with patients who use alcohol or other drugs heavily until they also decide to stop using these drugs destructively.

A Survey of Attitudes of Chairmen of Departments of Psychiatry Toward Community Mental Health

BY ANTHONY F. PANZETTA, M.D., R. BRUCE SLOANE, M.D., AND HARRIET ARONSON, PH.D.

The authors conducted a survey of chairmen of departments of psychiatry to determine their attitudes toward community mental health and the extent of their departments' involvement in community psychiatry. Among their findings were: a majority of departments had some association with a community mental health center (CMHC); the larger the department, the more likely such an association; a majority of departments offered training in community psychiatry to their residents; significant research in community mental health was carried on by a minority of respondents; most chairmen had a favorable attitude toward community mental health; and a majority of chairmen were congenial to having a CMHC within their departments.

THE FUTURE OF community psychiatry and that of the community mental health center movement is dependent on many factors, important among which is the attitude of chairmen of departments of psychiatry, particularly those within medical schools. Since the orientation of tomorrow's manpower is being developed today, it is important to assess how the leaders of our major training institutions view community psychiatry today.

There is a wealth of published material that takes either a protagonistic or antagonistic position regarding community psychiatry, but we have found no material on attitudinal surveys related specifically to departmental chairmen. Some of these chairmen have published material that reveals their own attitudes but we were interested in considering departmental chairmen as a group, rather than separately.

We undertook a survey to accomplish two broad objectives. First, we wanted data regarding the current level of operational investment by departments of psychiatry in the community mental health movement. Secondly, we wanted to assess the current prevailing attitude about community psychiatry—as expressed by chairmen of departments of psychiatry.

At the time this work was conducted, the authors were all with Temple University Health Sciences Center, Philadelphia, Pa. 19140, where Dr. Panzetta is Associate Professor of Psychiatry and Director of Outpatient Services. Dr. Sloane is now Professor and Chairman of the Department of Psychiatry, University of Southern California, Los Angeles, Calif., and Dr. Aronson is now Professor in the Department of Psychology, North Texas State University, Denton, Tex.

Dr. Aronson's participation in this work was funded in part by a grant from the North Texas State University Faculty Research Fund.

METHOD

A questionnaire was devised and then sent to members of the American Association of Chairmen of Departments of Psychiatry. The total number of possible respondents to our mailing was 95. We asked that the questionnaire be returned by March 1, 1971, although we accepted questionnaires returned as late as June 1.

The questionnaire, which was divided into three sections, was designed to be brief in order to increase the probability that the respondents would return a completed questionnaire.

Section I asked the respondent for: 1) his name, 2) the name of the medical school, 3) the number of years he has been chairman of that department, and 4) the size of the department, i.e., five or fewer full-time faculty psychiatrists, six to 15, or more than 15.

Section II presented 13 statements that the respondent was asked to rate "as to their adherence to your current assessment of community psychiatry." Because of the connotations of some questions, it was thought that respondents might select the "disagree" response if they were presented only with a choice between "agree" and "disagree." To avoid this bias we differentiated the agreement response to "agree totally" and "agree." In the scoring, however, no differentiation was made between the two. The 13 statements are arranged below according to the use made of them in scoring; in the questionnaire itself they were arranged as numbered.

Attitudinal

1. Community psychiatry is a distinct subgroup within psychiatry, characterized by its own relevant data, hypotheses, and methods of operation.

3. Community psychiatry should be resisted lest it undermine the gains thus far achieved in psychiatry.

4. The community mental health center is a desirable structure that can complement a psychiatric department.

6. Community psychiatry should be quietly ignored until it disappears of natural causes.

9. The community mental health center carries an inevitable service demand that can only *subvert* departmental priorities.

10. Community psychiatry offers greater potential for beneficial changes in psychiatric education than it poses dangerous threats to psychiatric education.

12. The community mental health center is unwelcome and it threatens the proper development of community psychiatry.

Origins of Community Psychiatry

2. Community psychiatry is a creation of federal funding priorities more than it is a result of social psychiatric research.

7. Community psychiatry has developed as a consequence of the findings of social psychiatric research.

13. Community psychiatry has a long history of growth, and the community mental health center movement evolved out of that growth more so than as a result of federal enabling legislation.

The Community Mental Health Center as an Intradepartmental Structure

5. The community mental health center is a welcome treatment structure but is more appropriate outside a psychiatric department.

11. Community psychiatry is an orientation with poor definition that would be more properly within the action arm of sociology or anthropology, if there were such an arm.

Dropped from Scoring Because of Ambiguity

8. Community psychiatry, despite its social and cultural implications, should focus its treatment on individuals and small groups rather than on population groups.

Scaling

The seven attitudinal items were converted into a scale, scored to indicate the relative positions of the respondents in their attitudes toward community mental health. There were two difficulties in the scaling: first, some of the respondents abstained from responding to one or another of the items listed and, secondly, we wished to weight each item to reflect the extremity of position that agreement or disagreement would imply. In order to overcome these difficulties, the scale was constructed in the following manner:

1. Abstention was weighted zero.

2. All other items were weighted in proportion to the percentage of chairmen responding in a dissimilar manner. Thus, if the chairmen were equally divided in taking a position for or against an item, those who were in favor of community mental health were given the weighted score of +50 and those who were opposed, a score of −50 for that item. On questions that elicited more extreme positions, the weights reflected the degree of extremity. For example, if the group split at 15 percent for and 85 percent against community mental health on an item, the respondents favoring it were given a score of +85, indicating they had disagreed with 85 percent of the respondents in maintaining their positive position, while those who were opposed to community mental health were given a score of −15, indicating they had disagreed with 15 percent of their fellows in maintaining their opposition.

3. The weighted scores were summed for all seven items, translated to positive numbers, and divided by ten for ease of statistical manipulation. These summed scores were used to assign each chairman a single score indicating his relative position on a continuum of attitudes. This score will be called the attitudinal scale score.

The scores fell into a curve with a range of 0 to 50, with higher scores indicating greater acceptance of community mental health and lower scores suggesting rejection. The mean score was 39.6, the median was 40, and the variance was 11.9. The curve tended to skew, producing a peaking of respondents at the higher end of the curve. The scale may therefore discriminate more finely at the lower end of the curve (against community mental health), which is the part of the population this study particularly wished to examine.

There was no attempt to offer an unequivocal definition of community psychiatry. Since community psychiatry is inherently an ambiguous concept, we wanted to allow maximal flexibility to the respondents; their responses therefore reflect their own understanding of the concept of community psychiatry.

Section III of the questionnaire asked the respondent to indicate whether or not his department was associated with a community mental health center (CMHC) and, if so, to indicate whether the department directly sponsored the center, whether they shared sponsorship with other institutions, or whether the center was completely sponsored by other institutions. We also asked that they indicate whether or not their residents and/or medical students participated in the program of the CMHC, and whether or not they offered a fellowship in community psychiatry.

Finally, we asked the respondents to indicate the extent of their current and proposed future levels of research in relation to the activities of the community mental health center.

FINDINGS

Of the 95 possible respondents, 80 chairmen returned their questionnaires (an 84 percent return rate). The results are based upon the information obtained from those 80 respondents, with an occasional reduction of the total number in cases of abstention.

Associations with Community Mental Health Centers

Of the 80 respondents, 56 indicated that their departments had an association with a CMHC and 24 indicated that they did not. Of the 56 departments with such an association, 16 were direct sponsors. The remaining 40 either shared sponsorship or were related to a center that was completely sponsored by other institutions.

The presence of an association with a CMHC (with or without direct sponsorship) corresponded to the size of the faculty of the department. Of those departments whose faculties numbered less than 16, 62 percent were

related to community mental health centers, while 83 percent of the departments with 16 or more faculty members had community mental health connections. This difference approaches significance using the chi-square test corrected for continuity ($p<.10$).

Community Psychiatry Training

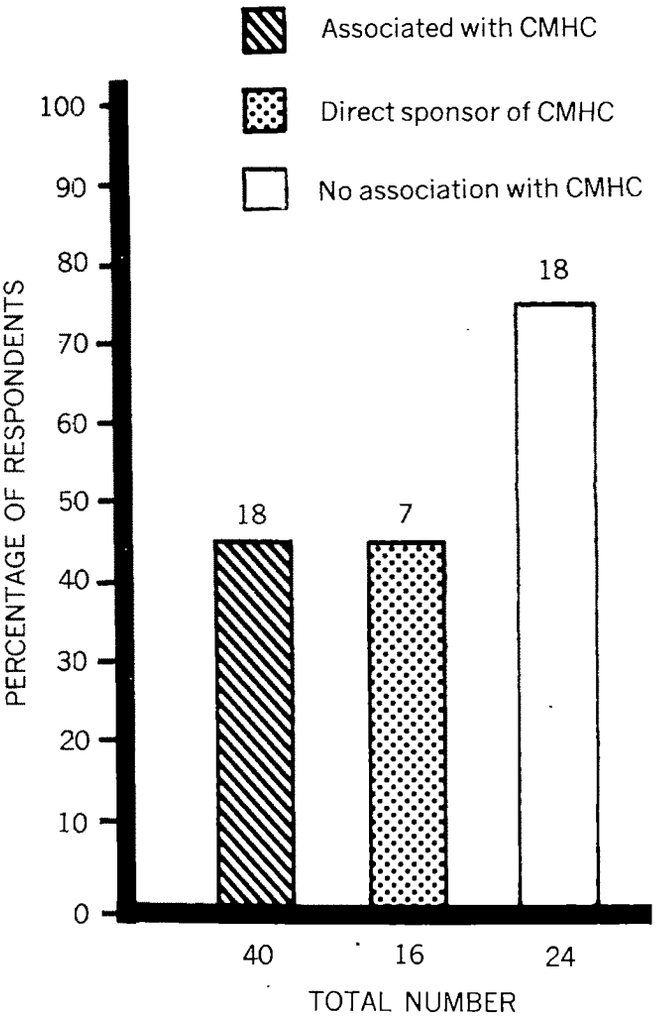
Whereas a large proportion (64 percent) of the chairmen indicated that their residents participated in community mental health center programs, they differed considerably in their attitudinal and operational investment. All departments directly sponsoring CMHC offered residents experience in those centers. One department offering such experience had no connection with any community mental health center and minimal involvement, either at present or in future expectation, with research related to community mental health. Of those 40 departments which were associated with community mental health centers but which did not directly sponsor the center, 34 offered their residents experience in the associated centers.

Medical students were offered experience in a CMHC by 44 departments (55 percent) while 35 departments (44 percent) offered no such experience. Fellowships in community psychiatry were reported to be available in 18 departments (23 percent) and not available in 60 (75 percent).

Research Investment in Community Mental Health

The chairmen were asked whether their current departmental research was unrelated or marginally related to community mental health centers or whether it was definitely or heavily related; all but one chairman responded. Forty-six chairmen (58 percent) indicated that departmental research was unrelated or marginally related. Thirty-three chairmen (42 percent) indicated that their research was either definitely or heavily related to community mental health.

Of the 56 departments with CMHC associations, only 30 (54 percent) indicated current "definite" or "heavy" investment in community mental health research.



When asked about future projections of their research investment in community mental health the group with definitely to heavily related research jumped from the current level of 42 percent to a level of 68 percent.

Attitudinal Findings

The attitudinal phase of the study focused on the overall attitude ratings and their comparison with the foregoing variables: CMHC associations, community psychiatry training, and research investment in community mental health. We also compared those factors with: 1) opinion regarding the origin of community psychiatry (i.e., federal funding, research findings, or general evolution), and 2) attitude as to whether a community mental health center is more appropriate in or out of a department of psychiatry.

1. *Overall Attitudes.* As noted earlier, the final scores on the attitude section were scaled from 0 to 50, with a mean of 39.6 ±11.9 and a median of 40. Of the 79 respondents who were rated, 17 (22 percent) had scores of 30 or less. These respondents could be considered as having the most negative attitudes regarding community psychiatry. Of these 17 respondents, interestingly enough, 13 have associations with CMHCs and two are in the position of sponsoring CMHCs.

FIGURE 1
Prevalence of Opinion That Community Psychiatry Is a Creation of Federal Funding, by CMHC Association

2. *Opinions Regarding the Origin of Community Psychiatry.* When asked whether "community psychiatry is a creation of federal funding priorities more than it is a result of social psychiatric research," 43 respondents (54 percent) replied in the affirmative. Thirty-one respondents (39 percent) felt that community psychiatry was not a creation of federal funding priorities; these respondents also felt that community psychiatry developed as a consequence of social psychiatric research and/or as an evolutionary outgrowth of long-standing trends. Five respondents (seven percent) were undecided.

When we contrasted the scores of these groups on the attitude rating scale we noted a significant difference. The

TABLE 1
Comparison of Attitude Scale Scores According to Level of Involvement with a Community Mental Health Center

Category	Number	Mean Score
Respondents without CMHC associations		
Congenial to CMHC within department	11	44.9
Prefer CMHC outside department	13	35.6
Respondents with CMHC associations		
Direct sponsor	16	43.8
Associated but not sponsor	40	37.7

group who accepted federal funding as the origin had a mean attitude rating of 37.88, as opposed to 42.94 for those who held the opposite position ($p<.05$, by two-tailed t test).

When we separated the direct sponsors of community mental health centers (16 respondents) from those who were associated but not direct sponsors (40 respondents), we discovered that being associated with a center (with or without sponsorship) did not correlate with a position against federal origin. The sponsors took a position against federal origin by a slight majority (56 percent), while the nonsponsors took a position for federal origin in 50 percent of the responses. But having no CMHC association was significantly related to a position favoring federal origin (see figure 1).

3. *Appropriateness of CMHCs Within Departments of Psychiatry.* When asked whether or not departments of psychiatry were appropriate sponsors of community mental health centers, 32 respondents (40 percent) answered in the negative, 43 (54 percent) felt the CMHC was welcome and appropriate within a psychiatric department, and four (five percent) were undecided; one did not respond.

As would be expected, chairmen who were congenial to the presence of a CMHC within their department showed a more favorable attitude toward community psychiatry (mean score of 43.9 versus 33.1). These same chairmen were more likely ($p<.03$) to actually sponsor a CMHC and even more likely ($p<.01$) to offer community psychiatry as part of the residency training experience.

When we compared the current research investment of the group preferring the center within the department with those preferring extradepartmental affiliation, we noted that the respondents from the "within the department" group were divided evenly as to whether they were not carrying on related research or whether they had significant to heavy research in community psychiatry. However, of the 30 respondents who claimed a heavy investment in such research, 73 percent preferred having a center within the department.

An interesting point emerged when the attitude of respondents was compared with whether or not they offered their residents experience in community psychiatry. We found that those respondents whose departments offered such an experience had a mean attitude score (39.6) identical to that of respondents who did not offer their residents experience in community psychiatry.

We did, however, discover a significant difference in attitude ($p<.05$) between those who had no community mental health center associations but nonetheless felt congenial toward having a CMHC within their department and those who neither had any CMHC association nor felt that one would be appropriate within their department (see table 1). Within the subgroup of respondents who had community mental health center associations, those who directly sponsored CMHCs tended to have significantly more favorable attitudes ($p<.10$).

DISCUSSION

What can we conclude from an analysis of these responses? It must be stated from the outset, of course, that we can generalize only with great caution. The instrument used in this study was not sophisticated and little can be said about its sensitivity or validity. However, it does seem reasonable to make certain statements that appear to be reinforced by the data obtained.

First, there is the straightforward counting of departmental activity with community mental health centers. The data show a great deal of such activity in general, although only a small percentage of departments have actually jumped in with both feet and directly sponsor CMHCs. We can also see that training in community psychiatry has become part of a solid majority of all residency programs. The data reveal, however, that community psychiatry has found its way into a bare majority of the curricula for medical students. What the quality or quantity of these experiences are like cannot be inferred from the data.

We did not discover a greatly resistant or hostile attitude toward community psychiatry and, if anything, the data suggest more congeniality than might have been anticipated. We were interested to note that community psychiatry is considered by a majority of chairmen to be a federal creation and that this connection is associated with a tendency toward a negative attitude.

Although promises for the future were great, current research investment in community psychiatry was marginal in most departments. This is not an encouraging sign if one takes the position that any new trend in psychiatry should be directed and supported by research. Since this survey focused only on medical school departments of psychiatry, we can say nothing about research in other settings. It is possible to speculate, however, that at least within the academic establishment, community psychiatry does not often enjoy the prestige associated with other research-worthy areas.

Modern Man and His Instinct of Workmanship

BY JUANITA M. KREPS, PH.D.

The author examines the place and meaning of work in contemporary American society, its relationship to the amount and quality of leisure time that is available, and its relationship to the worker's physical and mental health.

> No other technique for the conduct of life attaches the individual so firmly to reality as laying emphasis on work; for his work at least gives him a secure place in a portion of reality, in the human community.
>
> —SIGMUND FREUD (1, p. 27)

IN IMPUTING TO WORK a balancing factor, which contributes to the equilibrium of an individual (2), Freud nevertheless noted that "work is not highly prized by men. They do not strive after it as they do after other possibilities of satisfaction" (1, p. 27). Contemporary authors further stress the negative aspects of today's work; since most men work from economic necessity, they argue, work itself brings no sense of achievement:

> This is the tragedy of the human being, for it is only through work that he can exert his influence upon society. And while he rejects the amorphous, distasteful shape it has assumed today, he must subject himself to the lashes of necessity via the cash nexus. All that remains is a pecuniary reward, often of a pitiful nature, replacing the urge to undertake acitvity for its own sake. Humanity is thereby diminished (3, pp. 342–343).

Yet if work is so distasteful, why work so much? We could live well on far less income and presumably therefore with less time and effort spent on work. Given the rapid changes in the types of work we now perform—in particular, the trend from manual to white-collar, notably professional, jobs—it is well to reconsider the meaning of work, the reasons for man's persistent work drives, and the sources of frustration (and possibly health impairment) that attend the performance of today's most demanding jobs. Important questions pertaining to the relationship of work to physical and mental health, raised frequently in the past, take on new significance in the light of economic trends. On the one hand, higher productivity promises to free us from work for ever longer stretches of time; on the other hand, work apparently becomes more appealing as its content shifts from the manual to the mental, and this trend counteracts the decline in work emphasis.

If enthusiasm for work, because of its content or the professional or financial status it confers, comes to be even more central to life than heretofore, the leisure and health implications for some occupational groups assume added significance. In particular, as executives and professionals devote more and more of their time to work that is often quite stressful, thereby failing to share in the overall growth of leisure time, what impact does this work life-style have on their health?

THE DISAPPEARANCE OF WORKMANSHIP

Throughout the literature on work—the satisfactions, the monotony, and the alienation it produces; the role of monetary incentives; the impact of work on mental health—differential effects are imputed to various kinds of work and to different classes of workers. There is a strong tendency to assume that work satisfaction is maximized when the worker has a close and continuous relationship to the good he produces (note the glorification of crafts, for example), when the work calls for a high order of intellectual ability, or when some form of glamour, often physical danger, is involved. By contrast, jobs of low esteem are thought to be machine-oriented and mechanical, requiring little knowledge or skill, and allowing no exercise of ingenuity or personal judgment.

The association of work with physical unpleasantness is no longer a major factor in the disutility of work; relatively few jobs now require extremes of temperature or heavy manual activity. Instead of the physical discomforts formerly associated with most labor, today's workingman suffers from monotony, lack of control over the pace or content of the job, or a failure to perceive

This is an edited version of the William C. Menninger Memorial Convocation Lecture, read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Kreps is Professor of Economics, Dean of the Woman's College, and Assistant Provost, Duke University, Durham, N.C. 27706.

meaning in the restricted assignment of his tasks. Finer and finer divisions of labor, applauded by Adam Smith and subsequently perfected by two centuries of efficiency experts, rob the work of any breadth and the worker of any workmanship. In contrast to Veblen's "savage state," in which workmanship, i.e., the instinct to work efficiently, was dominant (4, 5), the motivation to work has come to be not work itself but the acquisition of wealth, which symbolizes esteem. Thus, according to Davis, Veblen reasoned that

> as the emphasis on competitive rating increased, any method of acquiring the desired symbols was accepted, provided only it promised success. Consequently a tendency to turn to force and fraud appeared. Success gradually came to be stated in terms of predatory exploit, and labor became dishonorable (6, p. 284).

But Veblen's conclusion that the earlier centrality of work has been subverted can be challenged. As Seligman pointed out, man continues to look for meaning in what he does: "Work is the most important activity in which man engages, for it provides *the* standard of judging his worth" (3, p. 338). Conflict arises when man attempts to impute meaning to work but finds that the technology that has increased productivity has also tended to render work mechanical and monotonous (3, 7):

> Meaning disappears as work takes on the character of a continuous process. When this happens those humans utilized by the process become mere automatons. And a civilization that distorts a human response in this manner is itself gross and distorted (3, p. 340).

THE APPEARANCE OF LEISURE

Deterioration in the quality and meaning of work has contributed to the drive for a reduction in the amount of time spent on the job. Time free of work for pay—frequently equated with leisure [1]—has grown dramatically during the twentieth century, the major change being in the length of the workweek. From an average of 53 hours per week in 1900, the workweek fell to 40 hours in 1970. Annual vacations, which account for a relatively recent growth in leisure time, increased in total amount by about 50 percent during the decade of the 1960s, with the average vacation for full-time workers growing from 1.8 to 2.2 weeks per year. Paid holidays have also grown in number; office workers now receive about eight paid holidays per year and factory workers about 7.5 (8).

Perhaps even more significant than reductions in the length of the work year is the number of years in which today's worker does not work at all. He enters the labor force much later in life and has several more years in retirement than his grandfather. Specifically, the twentieth century has brought an additional nine nonworking years to the American man, an increase of 50 percent in time spent outside the labor force. These nine years are divided about half and half between years in school and years in retirement. Since man now lives longer, his work life has also grown (in total, by about nine years); this increases the 1960 life expectancy at birth for men by 18 years, while women gain 22 years in life expectancy, with 14 going to paid work and eight going to further education and retirement (9).

Thus, technology is ambivalent in its consequences: it automates man and contributes to his alienation in work, while also increasing his output and allowing him time for other pursuits. Such time free of work is a luxury available to only a small proportion of the world's population. Retirement from work, along with the shortened workweek and later entrance to the labor force, are possible because man can produce enough goods and services to meet his family's needs in fewer than 12 hours a day—and in a work life shorter than one beginning at age 14 and ending with death. In less productive economies, it is not possible to subsist on the output of a short workweek, nor is it possible to keep children in school until age 18. Output is so low that all persons must work practically all their lives. Leisure in any form invites starvation.

THE QUALITY OF LEISURE

But just as the quality of work has depreciated under the relentless thrust of technology, so too the quality of free time is questionable. Contemporary views of leisure are hard to fathom. In contrast to Aristotle's belief that "the goal of war is peace, of business, leisure," the uneasy feeling that life with little work has little purpose pervades much of today's thought. Writers deplore the growing freedom from work, which provides "a great emptiness," devoid of meaning. Lacking training for leisure time and having no strong interest or devotions, persons without work lead dismal lives. The void created by free time has thus replaced "the days when unremitting toil was the lot of all but a few and leisure was still a hopeless yearning" (10, p. 54). On the quality of leisure, Seligman concluded that "leisure ought to be a serious activity; instead, it has been corrupted by the technology of industrialism and thereby converted into unfree engagements of time" (3, p. 356).

By far the most serious indictment of modern man's work-leisure patterns has come from Swedish economist Steffan Linder, who opened *The Harried Leisure Class* with the statement:

[1] The definitions of leisure are many. At one extreme, the term is used to refer to all nonworking time; at the other, it applies quite restrictively to that time which is completely free of commitments—in short, contemplative time. The concept of leisure as "discretionary time" has also been developed, and for many purposes this is the most meaningful use of the word. Nonworking time, or time free of work for pay, is used here; even this narrow use of the term does not preclude some definitional problems.

> We had always expected one of the beneficient results of economic affluence to be a tranquil and harmonious manner of life, a life in Arcadia. What has happened is the exact opposite. The pace is quickening, and our lives in fact are becoming steadily more hectic. It used to be assumed that, as the general welfare increased, people would become successively less interested in further rises in income. And yet in practice a still higher economic growth rate has become the overriding goal of economic policy in rich countries, and the goal also of our private efforts and attitudes (11, p. 1).

Since economic growth confers more income per working hour, man is urged on to work harder and harder as the price of foregone effort (i.e., free time) becomes more and more expensive. Thus time becomes increasingly scarce in relation to all its possible uses, and life takes on its modern hectic pace. In a similar vein, Wilbert Moore pointed out a decade ago that "in the world of common-sense experience the only close rival of money as a pervasive and awkward scarcity is time" (12, p. 4). Moore added, incidentally, that "loyalty or affection, too, turns out to be a universal scarcity upon close examination." It is probably not productive to apply the law of scarcity to loyalty or affection, but the basic principles do pertain to the use of time, as Linder illustrated.

As time comes to be more valuable, it is understandable that the use of each hour will be scrutinized carefully; one does not willingly "waste" time, not even when he is off the job. Consider the sale of consumer goods designed to reduce the time necessary for cooking, travel (even for pleasure), and personal and household maintenance. Other activities, such as visiting the indigent and caring for children and old people, are coming to be institutionalized in such a way that they often constitute work for pay; in the absence of such organized activity, the elderly in particular are likely to be neglected, for there is clearly implicit in our reluctance to provide adequate care for the aged the belief that such attention to their needs is wasted. Are their productive years not over? And does the allocation of time to their needs not fail to maximize the use of the time of productive workers?

WORK, LEISURE, AND HEALTH: SOME QUESTIONS

The constant drive to produce, to use time wisely, and to increase one's position or income through extra work pervades all we do. Playwright Walter Kerr noted that "we are all of us compelled to read for profit, party for contacts, lunch for contracts, bowl for unity, drive for mileage, gamble for charity, go out for the evening for the greater glory of the municipality, and stay home for the weekend to rebuild the house" (13, p. 39).

The important question becomes: is this modern version of the work ethic that now dictates the pattern of our lives, both on and off the job, the balancing factor once imputed to it? Freud's contention that work binds the individual closely to reality can hardly be questioned; men who are at work most of their waking hours indeed have "a secure place in a portion of reality." Moore's thesis that a man's perceived scarcity of time is an index of his integration into society (12, pp. 38–39) is a cogent observation of the same proposition. But is it not also true that this integration has become so complete, for a certain group of men, that it threatens to be unbalancing, that these men are so consumed with their work (in whatever guise) that they lose rather than gain balance?

The group in question has traditionally been small, relative to the total work force. From earlier studies by Wilensky (14), we know that the "long-hours" men are generally those with higher earnings, very often professionals and executives. One-third of the high-income men in his study worked 55 hours or more per week. Although there were some differences in work schedules among the professions, hours were high in most. Business executives, moreover, averaged a workweek of 50 hours, excluding business entertaining at home, travel time to work, and business travel. Being self-employed or Jewish or having a high income tended to raise the propensity for long hours. The fact that these men have not gained leisure during the 20th century's rapid economic growth, which brought significant reductions in working time to workers in general, prompted Seligman to comment: "The irony is that those whose productivity is highest work to support the leisure of those who are compelled to enjoy it" (3, p. 357).

One test of whether the work drive has become an unbalancing influence in the lives of the long-hours men emerges from examinations of the impact of work on physical and mental health. The importance of such an analysis is underscored by the recent upturn in the mortality rate for men. During the 1960s the course of mortality for both white and nonwhite men was upward for most age groups, starting at 15 to 19 years of age. Since the mortality rates for women did not rise, the trend toward excess mortality for men was resumed, after having leveled off in the 1950s (15). In the middle years, in which the man's work pattern would generally be most demanding, the mortality rate of white men in 1968 was double that of white women; heart disease accounted for three-fifths of the difference, with the mortality rate of white men from this cause being more than three and a quarter times that of white women. For white persons, the ratio of male to female age-adjusted death rates, which was 108 in 1920, has climbed to 175; for nonwhites, the ratio has gone from 97 to 163 (16).

The literature relating work to mental and physical health is overwhelming, ranging from detailed studies, such as Madigan's "Are Sex Mortality Differentials Biologically Determined?" (17) and his analysis of the impact of work satisfactions on the length of life of Catholic priests (18), to broader analyses of interdisciplinary research on the effects of the social environment on mental health (19). In the studies pertaining to work and mental health, attempts are made to appraise the meaning of work to particular groups of workers—those in factories (20–23) and those on farms (24)—and the effects of these occupations on the spirit and life adjustments of

workers. Kornhauser concluded that mental health [2] "is poorer among factory workers as we move from more skilled, varied types of work to jobs lower in these respects; and that the relationship is not due in any large degree to differences of pre-job background or personality . . . " (21, p. 46).

Other inquiries probing the relation of occupational status to physical and mental health have raised many questions, particularly on the issue of linkages between job stress and health. Studies have indicated that men under age 45 who are subject to intense competition, deadlines, long hours, etc., have higher cholesterol levels and a greater incidence of coronary artery disease than their counterparts in less stressful jobs (25). However, the studies also suggest that the stress may derive more from the worker's intense ambition than from the job itself. A key question is whether the problem lies in the confrontation of low job status with strong ambition; where jobs allow high accomplishments as outlets for high ambitions (as in the case of executives), health adjustments are permitted (25, p. 72).

The discrepancy between aspiration and achievement, and the impact of this discrepancy on one's self-image and ultimately on one's mental health, has been examined in numerous studies, following Merton's view of "psychiatric disorder as one possible adaptation to the disjunction between cultural success goals and socially structured opportunities" (26). From controlled studies, the evidence indicates that educational and occupational discrepancies exist more often, and are greater, among psychiatric outpatients than among nonpatients. Such studies confirm the majority view of psychologists that unrealistic goals are more characteristic of the mentally ill than of the normal person, and that of sociologists, who report that "unfulfilled ambitions are characteristic of the mentally ill" (27, p. 479).

THE SPECULATIONS OF AN ECONOMIST

The distinction between mental stress generated in the job itself, because of the work's pace, complexity, or degree of competitiveness, and that originating from personal ambition and unrealistic career goals is difficult to draw. It is clear, nevertheless, that men holding high-status jobs are deeply concerned with their performance in the work place; it is this arena in which such men are judged. Their preoccupation with work may spring primarily from a drive for financial gain, as Veblen argued, rather than from a devotion to the service being rendered. Indeed, there is a tendency to reason that pay provides the major motivation for work.

> Pay, in one form or another, is certainly one of the mainsprings of motivation in our society. The drive for private money gains—the profit motive—provides the main ideological cleavage in the world today. Deep down, everyone assumes that we mostly work for money (28, p. 3).

Among blue-collar workers, who are often unionized and who therefore voice common sentiments at the bargaining table, there is a clear preference for more work for pay rather than for more free time. The fact that these workers have gained time free of work is explained by the gradual decline in demand for their services and by consequent attempts to spread the available work. Competition for overtime work has been keen, even as the workweek was bargained downward. Similarly, the three-month sabbaticals available to steelworkers and the early retirements offered to automobile workers were attempts either to prevent involuntary layoffs or to create new jobs.

The world inhabited by the professional and the executive is quite different. There, the demand for personnel has far exceeded the supply during recent decades because the amount of work requiring professional or executive training has grown, not diminished. Moreover, the rate at which society could increase its supply of highly trained personnel has only begun to match the growth in demand for their services. As a result, there has been strong pressure on these groups to work longer hours and forego vacations—in short, to increase the time and effort devoted to work.

The difference between the blue-collar worker and the professional lies not so much in a difference in the amount of work preferred as in the availability of work, given the economic trends. But while both groups would seem to opt for more work, not less, the reasons for seeking additional work may well differ. If we are to take seriously the literature on alienation from work, we must conclude that most industrial workers see work simply as a means of livelihood; they find their meaningful activities in other contexts. But among professionals the centrality of work is quickly apparent.

If the growing group of professionals and other highly educated, work-motivated persons have the "pathological desire to toil," how different is this pathology from the instinct of workmanship that Veblen praised? Does the work drive, now bound up with personal ambition for status within the profession or with the financial success that in turn confers the aura of professional success, provide the balance that Freud attributed to work? Or have we reached the point where work has been swallowed up in the desire to achieve a status that only work, in our society, can confer? To what extent do we judge ourselves by the quality of the services we provide, and to what extent by the recognition our services receive? And finally, what is a healthy attitude toward work? To work more hours or fewer? To be motivated by a desire to provide service, or to make money, or to build a reputation?

It may well be that modern man, too, has a strong instinct of workmanship. Indeed, it may be that he is too concerned with work, too little committed to play, too scornful of the gay and the lighthearted. We live in an economy that can afford more relaxation from work than

[2] Kornhauser defined mental health as "an overall orientation and balanced relationship to the world which permits a person to maintain realistic, positive belief in himself and his purposeful activities" (21, p. 46).

its people seem willing to embrace. Clearly, we feel that the rewards from this life-style are great. But most of us have had little experience with the alternative, and all (save possibly the young) have quite forgotten that "the goal of war is peace, of business, leisure."

Social Psychiatric Impairment: Racial Comparisons

BY JOHN J. SCHWAB, M.D., NANCY H. McGINNIS, M.A., AND GEORGE J. WARHEIT, PH.D.

From a large-scale epidemiologic study of the mental health needs and services of a southeastern county, randomly selected groups of black and white respondents were compared with respect to social and demographic characteristics, symptoms and indices of psychological distress, effects of emotional distress on daily functioning, interpersonal and familial networks, aspiration and satisfaction, and a comprehensive rating of social psychiatric impairment. The authors relate the racial differences on these dimensions to social and economic deprivation and to social change in the South.

EARLY WRITINGS ON MENTAL ILLNESS among blacks in the United States, which first appeared in the 1890s, dealt primarily with the apparently rapid increase in the "colored insane." Witmer (1) noted that the subject of mental illness among blacks before the Civil War "received but little attention." Incredibly, the 1860 census reported only 766 "colored insane," most of whom lived in the North, out of a total black population of 4,441,830. The number increased to 6,776 in 1890, a change from 17.5 per 100,000 in 1860 to 88.6 per 100,000 in 1890.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are all with the University of Florida College of Medicine, Gainesville, Fla. 32601, where Dr. Schwab is Professor of Psychiatry and Medicine, Department of Psychiatry, Ms. McGinnis is Research Associate, Department of Psychiatry, and Dr. Warheit is Associate Professor, Departments of Sociology and Psychiatry.

This study was supported in part by Public Health Service grant MH-15900 from the National Institute of Mental Health.

Occupational category**		
Lower (service, private house workers, laborers)	49	18
Middle (clerical, craft, operative, sales)	11	45
Upper (professional, technical, proprietor, manager, etc.)	6	57

*The original sample N was reduced from 322 and the Ns listed here were reduced by missing observations or unavailable information and by the exclusion of three respondents whose race was classified as "other" (e.g., Oriental, American Indian, etc).
**Does not include housewives, students, unemployed, or retired persons.

Witmer (1), Babcock (2), Greene (3), O'Malley (4), and others (5, 6) believed that this increase was not a statistical artifact; they attributed it to the changed conditions of life following Emancipation—primarily removal of the black from the complete dependency of slavery and his introduction to the stresses of competitive life. Although most of such reports were based on fragmentary evidence or derived from anecdote, deleterious socioenvironmental factors were also mentioned. Unhygienic surroundings, sexual promiscuity, injuries sustained at laboring jobs or from intraracial aggression, and a poverty-stricken condition were considered responsible for high rates of psychosis associated with syphilis, trauma, and senility.

Fifty years later Malzberg (7) found that the rate of first admissions to state hospitals was higher for blacks than for whites. He concluded that environmental factors associated with poverty and segregated housing could provide "ample explanation of the high rate of mental disease among Negroes" (7, p. 394).

Of course these studies yielded information only about persons who entered treatment facilities; they cannot be used for analyses of prevalence. Particularly in rural areas, many mentally ill persons stay in the community, protected by cultural patterns or living as isolates. In their analysis of 44 field studies of social status and psychological disorder (8), the Dohrenwends found that only eight investigations presented white-black comparisons. They concluded: "There is no evidence of a difference in the studies comparing rates for whites and Negroes. Of the eight studies . . . four reported higher rates for whites and four for Negroes" (8, pp. 13–16).

But the Dohrenwends did find that the highest rate of psychological disorder is consistently in the lowest social class, many of whose members are blacks or belong to other minority groups. The purpose of this article is to compare the rates of social psychiatric impairment in blacks and whites in a random sample of a southeastern community.

DESCRIPTION OF THE STUDY

In 1968 we began a psychiatric epidemiologic study of a representative ecological area of the Southeast. The county has been undergoing rapid social and cultural change, as evidenced by accelerated population growth, urbanization, and the influx of a new technologically oriented, educated elite. With these changes the old and the new coexist. Despite the rural-urban shift, some blacks live in rural enclaves. Recent massive school desegregation has disrupted the entire community; and the deprived-affluent imbalance is striking.

Our general hypotheses are centered on the impact of social and cultural change on mental health and illness. Social change refers to alterations in the social hierarchy, occupational redistribution, and urbanization. Social change is intertwined with cultural change, which refers to alterations in life-styles, values, and beliefs. Our theoretical framework is derived in part from concepts of the "marginal man" developed by Robert Park (9) and elaborated by Stonequist (10). These early works depicted the mulatto or the Eurasian as the prototypic marginal person—straddling two antagonistic cultures but belonging to neither. With the massive social change and the culture lag about us, and with increasing sociopolitical polarization, the blacks, once perceived sociologically as a homogeneous group, are stratifying and holding various allegiances. In our work, therefore, we are concerned with this increasing marginality and with the mental health and illness of these more numerous marginal groups.

In view of the controversy about and the limitations of traditional models of mental illness, we are measuring social psychiatric impairment. This concept includes a so-

cial view of both mental disorder and deviance. Social psychiatric impairment encompasses psychosocial distress along four dimensions: 1) traditional definitions of psychopathology, reported as the presence or absence of symptoms; 2) levels of functioning at home, at work, and in the broader social arena; 3) the quality and quantity of interpersonal relationships; and 4) indices of aspiration and satisfaction. In our clinical research we are developing and refining this concept.

We interviewed a random sample of almost 2,000 adult respondents in a 900-square-mile county with a population of 100,000. Table 1 shows the demographic characteristics of the preliminary sample of 322 respondents.

Black males are underrepresented; the blacks are generally older than the whites; and substantially more of the blacks are widowed, separated, or divorced. The greatest differences between the races are that almost one-half of the black sample has an annual family income under $3,000, one-third has less than a ninth-grade education, and more than one-half is employed in a lower-status job.

The interview schedule, which took two hours to administer and contains 317 items, covered demographic data and a comprehensive social history; familial and other interpersonal networks; indices concerning religion, racial distance, anomie, and perception of social change; extensive physical and mental health inventories; and patterns of health care. Both black and white interviewers participated in gathering the data, and a number of local black consultants assisted us with the project. Three psychiatrists independently rated each of the 322 pretest protocols for level of social psychiatric impairment; their ratings were averaged for a composite score. (More than 100 psychiatric inpatients and outpatients were rated for purposes of validation.) Table 2 shows the impairment ratings according to racial distribution (N=322).

TABLE 2
Social Psychiatric Impairment and Race

Impairment Level	Black (N = 95*)	White (N = 220*)
Not impaired	58	159
Mildly impaired	30	48
Moderately impaired	7	13

*Ratings were not available for four respondents and three respondents of other racial categories were excluded.

RESULTS

Symptom Inventories and Items

On Z scores derived from anxiety and depression scales (11–15), more blacks than whites scored in the upper levels: high anxiety, 32 percent blacks and 22.5 percent whites; high depression, 29 percent blacks and 17 percent whites.

On the Leighton Twenty-Question Health Opinion Survey (16), 25 percent of the blacks, compared to 15 percent of the whites, scored above the cutting score for "possible cases."

There were no differences between the races on the following additional interview items: fear of nervous breakdown, feeling low and hopeless, nervousness, extreme restlessness, feelings of weakness, feeling frightened without knowing why, suicidal thoughts, and use of tranquilizers and sleeping pills. Only three items showed racial differences: hallucinations (blacks, 13 percent; whites, six percent) and feeling that people were trying to pick quarrels (blacks, 22 percent; whites, 14 percent) were more frequent in blacks than whites, but a larger percentage of whites (20 percent) admitted to excessive drinking than did blacks (11 percent).

Functioning

Major differences between the races were seen in reports on functioning. No differences were reported on the effects of emotional distress (e.g., worry) on work capacity. However, the blacks reported a greater number of days in the last year missed from work due to ill health; more often having to go easy on work because of poor health; not feeling healthy enough to do things more often; and that there were many times when they couldn't take care of things. In contrast, more whites reported curtailment of social activities because of mental problems (e.g., worry or fear of having a nervous breakdown).

Interpersonal Relations

More blacks reported that they had frequent contacts with extended family than did whites, and more blacks expressed satisfaction with these contacts. More of the whites indicated that they saw relatives infrequently; also, many whites were satisfied with such limited contact. On a three-point scale (seeing friends daily, sometimes, or rarely) almost equal percentages of blacks and whites reported daily contact, but a larger percentage of blacks than whites indicated that they saw friends rarely. When the respondents were asked whether mental symptoms such as worry or fear of a nervous breakdown produced problems with their families, more whites than blacks responded affirmatively.

Satisfaction and Aspiration

More blacks expressed satisfaction with their places of residence than did whites, and more blacks expressed dissatisfactions with their marital situations. There were no racial differences regarding satisfaction with present job. When asked, "If you could have any type of job you wished, what would you choose?" over 50 percent of the blacks selected service or similar types of occupations, probably reflecting both a low and reasonable level of aspiration, consistent with present educational and social opportunities. On this index the white sample viewed themselves as more upwardly mobile. But when asked, "How does the future look to you?" there were no significant racial differences.

The Cantril ladder (17) was administered to about one-

half of the respondents, each of whom was asked to locate his position in life on one of ten rungs in terms of the present, five years ago, and five years in the future. More of the blacks located themselves on the lower rungs five years ago and at present, but almost equal percentages of blacks and whites positioned themselves on the upper rungs five years from now.

DISCUSSION

One of the major problems with prevalence studies of mental disorders (other than psychosis) concerns the appropriateness of the criteria for evaluating the presence of mental disorders and the applicability of any one set of criteria to persons of different races or diverse sociocultural backgrounds. In our four components of social psychiatric impairment, some racial differences were observed. Consistent with the finding that more blacks were impaired, larger percentages scored higher than the whites on standardized scales. The minor differences between the races on some symptom items in the interview schedule can be attributed to cultural patterns, as can some of the greater differences on interpersonal relations. In terms of functioning, the most striking racial difference pertained to the deleterious influence of poor health on the blacks' work capacity. We suggest that the larger number of blacks expressing satisfaction with most aspects of life may reflect an acquiescent response set or a tendency toward replying with socially desirable answers—a style of responding indicative of the continuing influence of the caste system.

The finding that a substantially higher percentage of blacks (38 percent) than whites (28 percent) were impaired points to the magnitude of the health problems among black people in this southern community. Extensive illness of various types is prevalent among blacks. For example, our additional ratings for severity of *physical* illness showed that 64 percent of the blacks had definite physical illness, compared to 32 percent of the whites.

The applicability of our criteria of social psychiatric impairment to blacks in this community, and possibly the rating process itself, may be influenced by three major factors. First, impairment ratings may be confounded by the influence of physical illness prevalent in our black sample. Second, some differential cultural patterns are observable, but these appear to be shifting, concurrent with rapid social change. Third, acquiescent response sets and a tendency to give socially desirable answers are bound to be influential.

In view of these problems, we are undertaking further investigations to differentiate the effects of physical illness from social psychiatric impairment: The physical health status of 200 of our respondents is being evaluated by the Polyphasic Health Screening Center. Also, cultural differences and response sets are being assessed in follow-up studies.

An analysis of the rates for social psychiatric impairment in the races according to sex, age, educational level, and annual family income showed only a few major differences. Among the blacks, no sex differences in rates of impairment were found, but significantly fewer of the white men (19 percent) were rated impaired. A more striking difference was observed when the impairment rates were controlled for age. Over 50 percent of the blacks under the age of 30 (compared to 33 percent of the whites under 30) and 44 percent of the blacks over age 60 (compared to 28 percent of the whites over 60) were rated impaired.

Rates of impairment in both races were inversely related to educational level and annual family income. In both races almost one-half of those with less than a high school education and those with an income below $3,000 were rated as impaired, but rates declined to about 15 percent with higher income.

The physical and cultural deprivation associated with being poor and uneducated is apparent to anyone who travels through this county. The higher rates of social psychiatric impairment and poor physical health among the black population are directly related to poverty and little education. This correlation between lower social status and illness has been found consistently in other studies.

However, social structural relationships do not adequately account for the impairment rates—particularly the high rates of impairment among the young blacks in this county, which is in the midst of rapid social change. In a recent paper (18) McKinney and Bourque found that the rate of social change has been faster in the South than in the rest of the nation. Major regional differences, as measured by economic and social indices such as urbanization and occupational distribution, are rapidly disappearing.

We pointed out elsewhere (19) that the results of epidemiologic research must be viewed not only from a perspective of change but also with regard for the reciprocal influence of change. We think that one of the findings in this comparative black-white study highlights this point and has implications for increased understanding of the relationship between sociocultural processes and mental illness. Our results have consistently shown a curvilinear relationship between age and rates of social psychiatric impairment—higher among the younger and the older. Strikingly, 52 percent of the younger blacks were found to be impaired, compared to 33 percent of the whites. This is the single largest racial difference in any of our analyses for sex, age, education, and income. Furthermore, the high impairment rate among the younger blacks was not as directly related to low income as it was among the older group.

We think that the black young adult group have been exposed during their formative years to the sociocultural change that has taken place in the last two decades. As young people they witnessed the turbulence of America in the 1960s and participated in the struggles accompanying desegregation. But their opportunities for sharing in the life-styles and material benefits of the wider society displayed by the media were limited. At the same time, the protective traditional cultural patterns of the

southern black were being assailed on two fronts: subordinated and exploited by the dominant white society on the one hand and challenged and repudiated on the other by groups stressing an African heritage and Black Power and scorning the former accommodations to the caste system.

Some of the blacks, e.g., our younger age group, can be seen as experiencing conflict between competing sets of conditioned responses, such as parental restraints on assertion and aggression versus growing emphasis on pride in individuality and ethnicity. Such a situation produces cognitive dissonance and the dilemmas of the marginal man—a person caught between not only two different cultures but often many antagonistic cultures. "Spiritual instability, intensified self-consciousness, restlessness and malaise" were seen as characteristics of the marginal man by Stonequist (10).

We think that the rapid social change that has occurred in the Southeast is creating more and more marginal groups. In our major study of this county, which includes socio-anthropologic analyses of communities, we will continue to test possible relationships between social psychiatric impairment and marginality as well as the more conventional social structural relationships.

Drug Abuse, Sexual Attitudes, Political Radicalization, and Religious Practices of College Seniors and Public School Teachers

BY SAMUEL JANUS, PH.D., AND BARBARA BESS, M.D.

The authors surveyed a group of 745 public school teachers and compared them with college seniors in regard to a number of topics of concern to society today. They found that the use of drugs was more widespread among teachers than expected and that there was a close similarity between college seniors and teachers under age 30 in all areas examined. The authors point out the need for more studies on the attitudes and practices of teachers and on the effects of these factors on teaching programs.

THIS STUDY was designed to investigate drug abuse and sexual attitudes as well as political radicalization and re-

The authors are with the Department of Psychiatry, New York Medical College, Metropolitan Hospital Center, New York, N.Y., where Dr. Janus is Instructor and Dr. Bess is Assistant Professor and Assistant Director of Residency Training; Dr. Janus is also Assistant Professor of Psychology, John Jay College, City University of New York, and Adjunct Associate Professor of Psychology, Institute for Human Sexuality, Montclair State College, Montclair, N.J. TABLE 1
*Subjects Who Reported Themselves as Drug Users**

Category	Number	Percent
College seniors	264	61
Male teachers		
30 or under	158	66
31–40	72	43
Over 40	94	19
Female teachers		
30 or under	264	54
31–40	85	41
Over 40	72	14

*"Drug users" excludes both those who have never used drugs and those who have tried drugs only once.

ligious practices among a group of public school teachers. One of our main purposes is to offer a tentative evaluation of the behavior and attitudes of public school teachers and to contrast their attitudes with the responses of a group of college seniors. The paper is designed to determine whether a "generation gap" exists in regard to these important areas of life-style.

Teachers represent the largest single group of professionals in this country and, while their influence on the developing minds of young people is tempered by the influences of home, church, and peer groups and by the attitudes of society, they nevertheless are very significant disseminators and developers of ideas and models for identification.

METHOD

The population surveyed consisted of a group of 745 urban public school teachers, composed of 421 women and 324 men. The comparison group of 264 college seniors was drawn from a group of 880 respondents in a parallel study of college students from a large eastern urban university. The socioeconomic backgrounds of both teachers and students was primarily middle class. All subjects participated on a voluntary basis.

A 74-item questionnaire was developed to gather information in the areas of drug abuse, sexual attitudes, political radicalization, and religious practices. Candor was facilitated by guaranteeing anonymity to the respondents. The questionnaires were administered by fellow teachers and college students whom we had trained.

RESULTS

The results are presented in tabular form and are discussed with some of their implications. We consider it

TABLE 2
Relative Popularity of Drugs as Reported by Heavy Drug Users: Preference in Percentages

		Male Teachers			Female Teachers		
Drug	College Seniors	30 or Under	31–40	Over 40	30 or Under	31–40	Over 40
Marijuana	99	99	99	99	99	99	99
Hashish	36	23	24	7	32	20	4
LSD	16	10	8	2	8	7	0

TABLE 3
Attitudes Toward Petting and Sexual Relations Within Engagement

		Male Teachers			Female Teachers		
Attitude	College Seniors	30 or Under	31–40	Over 40	30 or Under	31–40	Over 40
Strongly agree petting is acceptable if the woman feels strong affection for the man	60	89	85	52	59	44	54
Strongly agree sexual relations are permissible for an engaged couple	50	73	67	32	53	27	35

of great significance that, although there have been a number of studies dealing with students in these areas of research, there is virtually no related research dealing with teachers.

For the purposes of this study, drug abuse is defined as the repeated use of nonprescribed drugs and/or the illegal use of substances that affect the emotions, perception, and mentation of the individuals who use them.

As shown in table 1, drug abuse reached a fairly high level among college seniors and remained high among young teachers, those under 30 years of age. Our results clearly show that, far from being in the minority, well over half of the teachers under age 30 were involved in the "drug culture." While there was a drop in drug use in the group aged 31 to 40, there was no dramatic decline until the group of teachers over age 40 was reached. In general, the teacher population seems to be a reflection of the larger society in terms of drug abuse. There is apparently no generation gap between college seniors and young school teachers (see table 2).

While the general order of descending drug abuse was from men under 30, at the peak, to women over 40, at the base, there were several notable exceptions. The use of both stimulants and depressants increased from college seniors to the groups of teachers over 40. The only category in which women's drug use sharply exceeded that of men was among those over 40 who used stimulants, where women reported five times as much stimulant use as men. There are two possible explanations for this: 1) they may have begun taking stimulants to aid in weight reduction, or 2) they may use them to counter the frequent depressions found among this age group.

Sexual Attitudes

Responses to items on this topic were measured on a six-choice scale ranging from "strongly agree" at one end to "strongly disagree" at the other. In general, the mass media stress that the predominant societal attitude is in such a state of flux as to be considered a sexual revolution. These sources hint at more promiscuity and liberalization of sexual attitudes in the youth culture than in the adult population. The impact of age in the responses shown in tables 3 and 4 is obvious, but it is instructive to note the correlation between drug abuse and sexual attitudes shown in table 4, where the responses are broken down on the basis of drug use.

As one might expect in traditional middle-class America, men in all categories were more permissive in their sexual attitudes. What is surprising, however, is the fact that teachers, who although young represent an older group than college seniors, seem to be more sexually liberated. This seems to contradict the general feeling that the sexual revolution is predominantly a youth-centered movement. Note that from table 4 it is clear that liberalized sexual attitudes increase dramatically in the drug-oriented youth and teacher groups alike. It would be closer to the truth to say that there does not seem to be a revolution but rather an evolution toward liberal sexual attitudes, and that age and education are important factors in this regard.

Homosexual Behavior

Once viewed with repugnance by both educated and uneducated people, homosexual behavior is now rapidly gaining acceptance and respectability among the "think-

Rarely, if ever	67	81	79	70	78	68	60

ing community." College students approved of permitting homosexual behavior between consenting adults by 48 percent, while teachers, combining all groups and ages, approved by 62 percent. It is important to note that this contrasts with the more traditional views of homosexual behavior, which are still held by lower socioeconomic groups.

Political Radicalization

Responses to questions in the area of political identification were arranged on a five-point scale in which 1 represented the extreme left wing and 5 represented the extreme right wing. Table 5 presents the subjects' stated political identification, with the students' group broken down to show the differences between those who do and those who do not use drugs.

While most subjects reported middle choices on the political scale, the factors tending toward identification with the right wing were increased age and nonuse of drugs. Conversely, those favoring identity with the left wing were youth and drug use. The shift in age is the more obvious if one notes the extremes, i.e., choices 1 and 5, in the various categories listed in table 5.

Religious Practices

Table 6 shows the dramatically sharp drop in the practice of any religious rituals in all groups; the decline was sharpest, however, among those who indicated the greatest level of drug use. The question of religious practice was posed as follows: "On the average I attend religious services: 1) once a week or more; 2) more than once a month but less than above; 3) I attend regularly, but less frequently than above; 4) I rarely, if ever, attend." This same question was posed in two ways, the first for childhood religious practices and the second for current practices.

Among college seniors who indicated substantial drug use we found that 87 percent rarely, if ever, attended religious services, while only seven percent attended weekly. In general, the practice of religion declined with increased education and declined sharply with identification with the political left wing and with the drug culture. The same trend was reflected in the religious practices of the teachers we surveyed and seems to indicate, as seen in table 6, that attendance at religious services also decreases with age.

DISCUSSION

It is evident that there are very close similarities in the extent of drug use, sexual attitudes, political radicalization, and religious practices among the college seniors and young teachers in our population. The pervasiveness of the values of the "drug culture," in all four areas studied, is also very obvious. There does not seem to be any generation gap between these students and our group of young teachers.

The involvement of this group of teachers with drugs is much larger than we would have expected. Even more surprising, considering the influence of teachers on youth, is the fact that there have been no studies that investigated the attitudes and practices of teachers in these important areas of life, especially in regard to drugs and sex. We emphasize here that we are describing the attitudes and behavior of the teachers themselves, but we have not yet studied the effect of these factors on teaching programs, or on young students in the elementary and secondary schools.

There are two major controversial issues in education today—sex education and drug abuse information in the classroom. Teachers' attitudes can have a major impact here. We are concerned with what should be taught in the classroom, but have paid little or no attention to the attitudes and characteristics of those who are teaching it. This area needs much further investigation. One can only speculate that the changing behavior and attitudes, of society and of teachers themselves, offer both positive and negative opportunities for investigation and teaching potential.

It seems to us that there is a great need for efforts to overcome the apparent lack of communication between teachers and society in general on these vital areas of life.

We need to evaluate the goals of education. For too long, teachers have been regarded as nonpersons and society has, with its aggressively "head-in-the-sand" attitude, created a sense of alienation in the educational community. We have sought here to show the need for an examination of the goals of education, especially higher education, as well as of the life-styles and attitudes of educators.

Implications of the Women's Liberation Movement for Psychotherapy

BY JOY K. RICE, PH.D., AND DAVID G. RICE, PH.D.

The authors examine the implications of the women's liberation movement for current psychotherapeutic theory and practice in terms of the antifeminine Freudian position, the predominance of male therapists, the concept of role unhappiness as psychopathological, and the threat to the therapist's social power. Consideration of role conflict in sociological terms instead of the intrapsychic rubric is especially emphasized. The authors also discuss related issues concerning the training of therapists and propose a model using male and female cotherapists.

CURRENT EFFORTS OF WOMEN to reexamine and redefine their personal, social, and sexual roles have important implications for many social institutions. The worlds of work, marriage, religion, and education have been scrutinized for their historical and contemporary contributions to the perpetuation of an inequitable system of sexual discrimination that penalizes women. It seems likely that few institutions will come through unscathed and unchanged as a result of this penetrating social analysis. We do not agree with many of the psychiatric and other critics of the women's movement who characterize it as a passing fad of upper-middle-class females or unmarried neurotics and assign it little impact (1).

In our experience, the appeal of women's liberation to a woman's sense of dignity and the possibility of enhanced self-esteem are very powerful attractants; indeed, the potential gain is often seen by many women as outweighing major initial risks, e.g., feelings of greater frustration with their lives, increased anger toward men, and the need for significant restructuring of their basic relationships with men. Although women might increasingly seek psychotherapy as one means of coping with conflictual role demands and expectations (2), at the same time certain tenets and stereotyped practices of therapy may produce a growing dissatisfaction with therapy as a conventional solution to personal conflict. To the extent that psychotherapy represents a social institution, it too must be carefully examined in regard to its views and attitudes toward women. The following aspects of traditional psychotherapeutic theory and practice seem to have important implications for women and their desired role changes.

The authors are with the University of Wisconsin, Madison, Wis., where Dr. J.K. Rice is Clinical Psychologist at the Student Counseling Center, 415 W. Gilman St., Madison, Wis. 53706, and Dr. D.G. Rice is Associate Professor of Psychiatry, University of Wisconsin Medical School.

CRITIQUE OF PSYCHOTHERAPY

The Antifeminine Freudian Position

Since Freudian theory and practice represent one of the major bodies of psychotherapeutic knowledge, the effect of the Freudian viewpoint concerning female behavior is considerable. Without disputing the great contributions of Freud to contemporary psychiatry concerning (among other things) the nature of consciousness, the phenomena of repression, and the significance of dreams, it is clear that, as Robert Jay Lifton was quoted as saying, "Every great thinker has at least one blind spot; Freud's was women" (3). The classical psychoanalytic theory of sexuality is male oriented, and Freud's taxonomy labeled women as the "abnormal" sex. What is more significant, however, is how anatomical differences have been built by psychoanalytic theorists into a powerful system of psychological, moral, intellectual, and societal values that transcend mere physiology (4).

The many disparaging references to women that can be found in even a casual perusal of Freud's work are tribute to the complex system of sexual values and status erected by his appeal to biology. At various times, women were described by Freud as "less ethical, with less of a sense of justice, more envious, weaker in social interest, more vain, narcissistic, secretive, insincere, masochistic, passive, childlike and incomplete" (3). For Freud, they were clearly an enigma ("What do women want?"). The repu-

diation of clitoral orgasm as second-rate, in the recent work by Masters and Johnson (5), represents a dramatic demonstration of the basic male Freudian bias.

Present-day therapists, while vocalizing a more liberal stance, often betray similar underlying prejudice. Bettelheim said that "we must start with the realization that, as much as women want to be good scientists or engineers, they want first and foremost to be womanly companions of men and to be mothers" (6). Rheingold wrote: "Women are the fountainhead of nurturance. . . . When women grow up without dread of their biological functions and without subversion by feminist doctrine and therefore enter upon motherhood with a sense of fulfillment and altruistic sentiment, we shall attain the goal of a good life and a secure world in which to live it" (7, p. 714).

It is unlikely to be acknowledged by women who seek the help of the Freudian-oriented therapist that Freud's position was in a large part a product of Victorian, Viennese social thinking (3). Moreover, they may not know or believe that psychoanalytic theory could be flexible enough to permit insightful present-day therapists to modify and adapt Freud's views in accordance with more contemporary findings about feminine behavior. The wide dissemination of the view that therapy is "antifemale" (not an unrealistic public generalization of Freud's position) is likely to result in fewer women perceiving psychotherapy as an available resource for solving personal problems.

While the close banding together of women in groups to solve their own problems may be one solution, this does not seem likely to relieve many of the emotional problems of women that require the skill of a trained psychotherapist. A better alternative would be an emphasis on the modifiability of Freudian theory and a willingness of Freudian-oriented and other therapists to be open to a healthy redefinition of female sexuality and role behaviors in accordance with contemporary knowledge. This position will be expanded more fully in the sections that follow.

The Predominance of Male Therapists

The delay in recognition of the antifemale bias in much of traditional psychotherapy could well be related to the fact that, as in other professions (e.g., law, the ministry), a disproportionate majority of practitioners are male. Many of the women's rights organizations have questioned whether a male therapist can understand and accept a woman's innermost feelings and communicate such an acceptance in a way that facilitates personal growth. One is reminded of the argument of the blacks, who insist that true communication is possible only with other blacks. In their more candid moments, our male therapist colleagues confess to feelings of perplexity and inability to feel the same degree of understanding and predictability in regard to the behavior of many of their female patients as they do toward their male patients.

The perceived inability of male therapists to understand women is likely to be increased rather than diminished by the shifting role sets and expectations promulgated by the women's liberation movement. Women patients' sense of frustration is likely to be enlarged both as a result of personal changes in role expectation (2) and from a sense of distance and lack of understanding felt between themselves and men—male therapists included.

A common result of a woman's increased awareness as to her traditionally expected role and "place" in what she perceives as a male-dominated society is a sense of generalized hostility toward men. The male therapist is not likely to escape these feelings. Such awareness is likely to increase the customary perception of patients that they are at times being exploited by the therapist (for their money, for revealing their personal feelings, etc.). The traditional interpretation of such perceptions in terms of transference ("These are really feelings toward your father, brother, husband, etc., that you are now generalizing to me") may seem less and less a satisfactory explanation. Although the original prototypes of such emotional experiences were probably in the primary family setting, they have been perpetuated to varying degrees by the male-dominated social context in which the woman patient has lived. Since it is likely that male therapists (as a product of our society) share certain chauvinistic attitudes at present, part of a woman's greater feelings of hostility toward men, including her therapist, seem appropriate and justified. Such feelings should be honestly acknowledged and dealt with in the therapeutic relationship. In fact, it is in the therapy situation that a woman's generalized feelings of hostility toward men might be most appropriately expressed, accepted, and worked through.

Role Unhappiness as Psychopathological

The mental health professions have long been vulnerable to criticism that part of their role is to help individuals "fit into society." Although psychotherapists have often admired and nurtured individuality, they have remained cognizant of social norms and sexual stereotypes (8, 9). Much effort in therapy has been to help patients achieve a comfortable "fit" with these traditional behaviors. This seems a natural tendency as long as one's definition of normality relies on a statistical formulation, with behavior different from the majority labeled as "deviant" (9).

One result of this position is that a therapist may begin to look for signs of psychopathology when he sees a woman who expresses marked condemnation of traditional feminine role expectations. This phenomenon is accentuated in the general public, which is quick to label advocates of women's liberation as lesbians and believe that this deviant tendency (irrespective of whether it is true or not) "explains" their reason for questioning the traditional role of women. The problem is similar for anyone in the avant garde of a social movement; labeling such an individual as deviant "explains" why they are doing their "unnatural" thing. Labeling role conflict as psychopathological and interpreting it in intrapsychic terms underscores the basic failure of most therapists to appreciate the social context that forces a subtle

"schizophrenia of person" for a woman. The latter is perpetuated by a variety of forces:

1. The traditional role we prescribe for a female is maternal and sexual (10, 11); the role of another's identity: "I am _____'s mother; I am _____'s wife; I exist because I am needed by someone else who is real." When children grow up, the mother is again no one. Even the pretense of real identity is lost.

2. The feminine housewife role glorified by the media and society is more than unrealistic, it is a hoax. The irrelevance, futility, repetitiveness, and goallessness of most day-to-day activities presently associated with being wife and mother are simply not recognized.

3. Most of the highest rewards within our society are held out for the achievement roles, the path traditionally associated with men. The movers, the innovators, and the creators are the ones who are esteemed (12). Thus, while the role of mother is given much sanctity in our society, a woman is given virtually no formal preparation for taking care of children. Indeed, the job of child-care worker is put at such a low premium in American culture that we assign it no professional status and ignore the fact that we are the only large industrialized country in the world without a public program of child-care facilities (13).

4. The temptation to be an *object* rather than a *person* is strongly reinforced by a consumer society that commonly assigns a predominantly erotic role to a woman. The concomitants of the cult of beauty and youth are that if a woman cannot attract a man, she is nothing. Not only are others' evaluations of self given highest priority, but internalized selfhood is ignored and the status of object rather than person is further glorified. Consumption of other objects becomes a substitute for identity and for relationships (14, 15).

5. A woman's self-image is deeply affected by societal programming of double-binding behaviors that tell her to be sexy, yet a virgin; strong, yet weak; subordinate, yet challenging (16); smart enough to get a man, yet needing to hide her intelligence (17); to achieve in school, yet to "fail" in the world of work (18).

6. The devaluation of the personal characteristics and qualities associated with being a woman has been well documented (8, 9). It seems obvious from this conditioning that the masculine stereotype might appeal to a woman as a more valued mode of living and that empirical studies consistently find femininity in females associated with poor adjustment (19). Such women frequently go to therapists with complaints of low self-esteem, chronic depression, and lack of identity (20).

These points have documented the schism that American culture forces upon a woman: She is overtly told to love herself and her role, yet covertly taught to hate herself and her sex. The stereotyped, intrapsychic interpretation of such self-abnegation without full cognizance of the societal influences that perpetuate the conflict not only represents a narrow approach, but can also be a destructive reinforcement of the status quo by the therapist.

We suggest that a careful questioning of role is a healthy, rather than a pathological, process for a woman or for a man. (We have attempted to document the kind of role stereotypes that force a schism for women, but men are equally victimized, as elaborated by Brenton [21].) Such role examination would lead, we hope, to greater ultimate happiness and self-satisfaction and not to a lasting feeling of abnormality. In fact, if there were a healthy societal acceptance of role questioning and the concept of flexible role change, the process would occasion little anxiety and turmoil. Many women would then not consider psychotherapy as a response to the feeling "Something must be wrong with me." Until society adjusts to this idea, however, many women will continue to feel that the desire to change the expectations and patterning of their lives is an indication of personal problems. In response, therapists will continue to prescribe love as a substitute for action (22), and interpret the search for identity as a running away from closeness (1).

A more fruitful therapeutic course would be to help a woman question, probe, and recognize the historical, environmental, familial, and societal antecedents that can often precipitate and perpetuate feminine conflicts; aid her with the restructuring process necessary in her primary and personal relationships, especially her marriage; provide a place where feelings toward men and about women who stand for the traditional feminine role patterns can be ventilated and explored; and assist her in exploring new roles and models.

Recent papers by Mitchell, Rossi, Brown, and others (23) have put forward varied alternatives to the family that include the legitimization of a number of different forms for intersexual and intergenerational bonding; the promotion of part-time work for both men and women; the acceptance of the legal legitimacy of all children born, regardless of the marital status of their parents; equal division of all tasks within the family; and free birth control, abortion, and 24-hour child care. A bill that would provide for a three-year renewable marriage contract has been introduced into one state's legislature. Egalitarian marriage or union in which both husband and wife maintain careers that carry equal importance and an equitable division of labor determined by preference or agreement is becoming more than a utopian anomaly in American life (24).

The reaction to these proposals and innovations has been less than favorable among many mental health professionals; it has even been hostile. Some see the difference between the two sexes as disappearing at an alarming rate and conclude that many societal ailments stem specifically from the lack of clear sexual roles (25, 26). Even as eminent an author as Erikson insisted on the stereotyped precept of womanly fulfillment: A woman "harbors an 'inner space' destined to bear the offspring of chosen men and with it, a biological, psychological and ethical commitment to take care of human infancy" (27). This view can be seen in actual practice in Boston, where women are denied entrance to a mental health training program if they work full-time or have a preschool child (1). And the president-elect of the American Academy of General Practice, addressing the Wisconsin division, was quoted as asserting that a woman is preferable as a physician's aide because she is more obedient and is

taught to be subservient to doctors: "This role is suited to a woman" (28).

Such dogmatic pronouncements of women's "true nature," and the lack of acceptance of possible major changes in marital, familial, and sexual behavior and patterning, are likely to result in many therapists being seen as inhibiting and condemning rather than freeing by many women patients. To remedy this, the therapist (who may be more cathected and involved in the traditional system) must be carefully and honestly attuned to his own feelings. He must not only become knowledgeable about the process of his own social conditioning, which influences his attitudes and beliefs, but he must also become cognizant of the inherent social or personal gains he may accrue in resisting change.

Threat to the Therapist's Social Power

The demand of women for equality as individuals can form a distinct threat to the therapist's sense of social power. Because of the nature of the therapy situation, it is very easy for the patient, in the role of supplicant, to feel "one down" in power to the therapist. In some instances the elevation of the therapist (as the key person who can provide the answers to troubling problems) is valuable in that it reinforces the therapist's sense of self-worth and helps sustain his or her motivation for what may be an arduous and painfully slow process of human growth. However, a woman seeking feelings of sexual equality and experiencing the conflictual urges of newly aspired role freedom does not easily accept the conventional power structure of psychotherapy. Therapists are likely to feel on trial early in the therapeutic relationship, and their mettle is tested as to whether they truly believe in and can permit a relationship of equals.

For a therapist accustomed to the traditional male and female psychotherapeutic role patterns, this can be a jarring process. Labeling verbal aggressiveness as "masculine striving" or "transference resistance" may simply serve to reinforce the male therapist's own power position, and such interpretations might fall on deaf ears. At this point many women patients could feel that the therapist has little to offer that is different from traditional answers and could well leave therapy.

The traditional blank-screen, silent approach favored in the analytic therapeutic mode is particularly conducive to fostering regression, dependency, and distortion; it often serves as well to maintain the inscrutability and superiority of the therapist. While there are advantages to this approach—e.g., in breaking down defenses—unfortunately the concomitant result is often to reinforce the neurotic behavior patterns that distress many women, namely the passive infantile mode, reluctance to action, and the preference for the "irrational" approach.

To cite another example, the client-centered approach, which emphasizes a nonjudgmental, unconditional acceptance of the individual, can crucially fail the woman who comes to therapy goalless, indecisive, lacking identity, inspiration, or simply the information needed to search out new personal modes or solutions, We see the therapist as a knowledgeable, active participant in the therapeutic process, and his or her training and experience need to reflect these new values and emerging societal trends.

IMPLICATIONS FOR TRAINING

Discussion of the possible effects of the women's movement on traditional psychotherapy leads us to a consideration of several issues and implications for the training of therapists. Specifically, we see the need to train therapists to fill a greater number of roles:

1. As experts on the growing body of research into sex differences and the psychology of women. There is much recent literature and empirical work on the psychology of women, changing sex roles, and established sex differences and how these differ from the myths in this area. Other writings document the effects of sexual discrimination, its cultural and societal antecedents, and the need for change (29, 30). Most contemporary therapists have little formal knowledge of these findings, and few current mental health training programs give their students instruction in this increasingly important field. Moreover, therapists get little practical experience (other than from their spouses) in exploring these areas from a feeling standpoint. We urge that didactic courses dealing with the psychology of women be established as a core part of psychotherapy training programs. Moreover, sensitivity training groups of men and women structured to explore sexual role patterns and expectations and to evaluate personal sex role bias would appear to be a valuable training device, both for experienced and novice therapists.

2. As open proponents of alternative life-styles and sex roles. Therapists may make more errors of omission than commission; the strong emphasis on listening and analyzing and the reluctance to provide direction for fear of imposing values may promote little impetus for patient change. Many therapists tend to be passive when confronted with social issues requiring innovation or change. It is much easier and more comfortable to silently support the status quo under the guise of neutrality than to encourage "deviance." Yet the active supporting of "deviance" may be precisely what is needed to effect a more healthy behavioral pattern and social identity for today's woman.

How many therapists would explore the role of a single parent or a single career woman, would suggest an occupation or life role that could conflict with a marital role or inconvenience a husband, or would be prepared to discuss honestly the ambivalence and schism in traditionally defined sex roles? Furthermore, in contemplating alternatives to these roles, few people, including therapists, would consider anything other than an achievement model for a meaningful possibility. Yet the socialization of men into the achievement model is as narrow a perspective as the socialization of women into the maternal one, and the extraordinarily widespread dissatisfaction of men who at age 35 or 40 have achieved their original goal(s) of fame, affluence, or status is poignant testimony to the futility of rigid adherence to a single model.

We suggest not only that the therapist must be prepared to discuss these issues, but that he also may have to take the initiative. Consider that a type of patient frequently seen in private practice is the fortyish, depressed, passive woman who exhibits a general frustration, boredom, and masked anger. She is not likely to be the female activist who has questioned her role and has already embarked on a course of action (the activist is more likely to be angry than depressed and to be vocal in her analysis instead of aimless and articulate in her complaints). The therapist who plays out parental socialization practices by a continuing pattern of protectiveness may be of minimal help to these female patients. Women need to be confronted when they harbor unrealistic visions of the traditional role, must be encouraged to explore the nebulous routes to self-esteem, and even "kicked out" of the womb in order to experience successes and failures in a real competitive world.

3. As community agents of social change. In terms of the numbers of individuals that one could help, or the influence for social good that one could effect, sitting in an office doing psychotherapy will perhaps never accomplish what getting out of the office might. Working in caucuses, lobbying for legislative change, educating the community, and working with influential groups and with lay groups are likely to be where the ways and means of change lie. Young professionals in a variety of fields are choosing this route increasingly. Lawyers seek the ghetto, new M.D.s bombard the American Medical Association for social reform, abortion, and health care, and clergymen become "politicians" in recognition that the ivory tower of the office is not "where it's at." Aiding a handful of individuals to paths of greater self-esteem and personal fulfillment within one's lifetime can of course be personally rewarding and meaningful, but if our goal is to achieve a truly egalitarian society, we must do more. The provision of community, consultative, and political experiences for trainees is one solution; yet, more importantly, our training programs must reflect the recognition of the therapist as an agent of social change.

Also, there is an obvious need to train more women therapists. At present about 11 percent of the American Psychiatric Association and about 25 percent of the American Psychological Association membership is female. Encouraging more women to enter the mental health fields at the higher professional levels will require reaching them through high school counseling programs, education of the parents and teachers who influence career choice, active recruitment of female trainees within professional schools, and adoption of more flexible admission policies.

Advantages of pairing a female therapist with a female patient struggling with conflictual role demands in a changing society include a greater sensitivity to issues and an ability to empathize with feelings; the provision of a role identification model; and the offer of potentially important solutions that may stem from the therapist's own personal experience. The woman therapist could also effect change in male patients by directly confronting chauvinism and sexual stereotypes within the immediate relationship. These advantages depend on the attitudes of the female therapist for, as is apparent from the literature cited, many female professionals support the status quo as vehemently as do some of their male colleagues. However, even if there were some magic way to equalize the number of male and female therapists available, until present sex typing and biases are changed, research evidence seems to document that male therapists are likely to still be preferred over female therapists by both sexes (31, 32).

ALTERNATIVES TO TRADITIONAL TREATMENT METHODS

The increased use of couple or group therapy with male and female cotherapists seems a ready solution to many of the critical issues discussed in this paper. Such a therapeutic arrangement allows for a full and open exploring of feelings related to changing sexual role behaviors in the presence of an "ally" (a sympathetic therapist of the same sex). The success of this procedure depends on the two therapists' awareness of and comfort in dealing with each other and with the issues for the therapist raised in this paper.

The greatest impact of the feminist movement as related to psychotherapy seems likely to be felt by the younger married women. Such individuals have made certain choices in the direction of traditional feminine role values but do not feel their life pattern to be set in a way that prohibits reevaluation and change. Such women seem prime recipients of the conflict engendered over changing feminine role demands and expectations (2). The results of this self-exploration process are likely to demand a major restructuring of the marital relationship. The male and female cotherapist treatment model proposed would seem especially appropriate for such cases, with both husband and wife seen together.

However, psychotherapy per se, despite its context, may not be the solution for many cases. Therapists must be prepared to recognize and even to suggest other more viable alternatives to psychotherapy when appropriate. A woman with role conflict might well make more progress in a consciousness-raising group of other women, and would benefit by a referral to helpful agencies or individuals. Such groups essentially function as encounter or sensitivity groups. Being a woman is given positive support, models to follow are provided, and attempting more effective role behaviors is encouraged. Guilt may be dramatically reduced as a woman comes to realize in such a group that her "personal" problem is in part a societal one.

Black Liberation, Women's Liberation

BY ANDREW E. SLABY, M.D., AND JOAN R. SEALY, M.D.

The authors interviewed 74 randomly selected college students in an attempt to determine reasons for black women's lack of involvement in the women's liberation movement. Black female students showed a great concern with blackness and its implications but less concern than their white counterparts about integrating vocational interests with their concept of their sex role. It was noted that the black students' fathers were often of lower occupational, educational, and social status than their mothers. The possible implications of these findings are discussed.

THERE HAS BEEN a conspicuous absence of any significant involvement by black women in the women's liberation movement. This seems somewhat ironic since the rhetoric of the movement often includes allusions to the concept of the "woman as nigger," suggesting that a woman's plight in America is somewhat similar to that of blacks. The question of liberation as women somehow does not appear to be relevant to black women now or, if it is relevant, seems of less importance than their liberation as blacks.

At first glance the lack of affiliation between the two ostensible minority groups might seem incongruent with the observations of some (e.g., some women liberationists) that the two are sister victims of a predominantly white patriarchal social system. Yet comparisons be-

At the time this work was done, the authors were Postdoctoral Fellows in Psychiatry, Yale University, New Haven, Conn. Dr. Slaby is currently Clinical Associate, Laboratory of Clinical Psychopharmacology, St. Elizabeths Hospital, Washington, D.C. 20032. Dr. Sealy is with the Department of Psychiatry, George Washington University School of Medicine, Washington, D.C.

The authors wish to thank Dr. Kenneth Keniston, Professor of Psychiatry (Psychology), Yale University, for his helpful criticism and Ms. Jane Keane for her assistance in the preparation of this manuscript.

tween the two movements are increasingly coming under criticism. It is true that blacks and women not infrequently encounter comparable employment difficulties when presenting credentials, skills, and experience equivalent to or greater than those of white male applicants. However, American women are generally not segregated from the so-called oppressive male subculture while growing up, and in addition, women form approximately 51 percent of the population, while blacks constitute only 11 percent (1).

Other clear differences between the two subcultures often overlooked by overzealous advocates of a union between the two movements have been discussed by women such as Anne Osborne of the Southern Christian Leadership Conference in Atlanta, Ga. Reflecting on the apparent reluctance of black women to participate in the liberation movement, she explained that black women are "just beginning to get the kind of good treatment as women that white women have always had. They don't want to give it up too fast. Black men have just gotten enough money to take them to nice places, and women like it" (2).

The literature on the women's liberation movement provides other suggestions for a basis of distinction between the two egalitarian movements. Kate Millett has contended that, given a patriarchal society, women are taken less seriously than men intellectually, are seen primarily as sexual objects, and are deemed less powerful in the marital contract (3). However, it is not clear that these points are as applicable to the black subculture as to the white. Billingsley, for instance, has said that there is a stronger tendency toward mutual aid in black family life as a consequence of the black subculture's subordinate position in the largely white American society (4). If this indeed is so, then it would not seem surprising that most black women reject a major concern for liberation as women at present and instead devote their energies to the more general liberation of the black people.

Other factors possibly contributing to the general absence of blacks in the rank and file of the women's liberation movement emerged during interviews of 74 students who entered Yale College in September 1970. These students have been interviewed serially during their freshman year and again during their sophomore year in an attempt to identify psychosocial origins of student commitment and alienation in the early 1970s. All of these randomly chosen students consented to be in the study and have remained in it. There are 32 blacks and 29 women in the group.

BLACK IDENTITY

It is striking that, when talking with black women, one repeatedly hears allusions to blackness, but none to involvement with women's liberation. Interviews are replete with references to the subjects' own blackness and their concern for their black "sisters" and "brothers." For instance, one black woman, when asked what she expected to be doing 20 years from now, stated, "I'd like to be involved in the black community and feel 20 years from now I will be." The sincerity of her response was evidenced by her present involvement as an officer in a black organization on campus. Another black student, when asked about the role of politics in her life, expressed concern for black youths looking for easy solutions to racial problems: "I'd like to be an activist, but I'm disgusted with the way things are. I think it is the height of arrogance for college kids to call Americans this and that and racist and all. I'm more concerned with the black people."

Many felt that the concern with blackness contributed to the formation of all-black groups that interacted little with white students. Commenting on this phenomenon, one black student said, "Three-fourths of blacks will just stick around with blacks. Although they may occasionally be with white friends, they eat with blacks and also party with blacks, and if they take gut courses, they try to take them with blacks." Another black woman student gave a rationale for the formation of a separate subculture and also for the choice of Yale as a college by some black students. She said, "My friends are from the same ethnic background; it's less complicated . . . especially since not everyone believes in U.N.-type relationships. Some black students came to Yale explicitly to meet other black students who are achieving academically at the same level."

It would be misrepresentative to state that these young women were not concerned with the issues of womanhood, but they had no major concerns about the oppression of women. Attitudes toward women's liberation among black coeds ranged from that put forth by one who, when asked how she saw the concern for the environment and ecology, commented, "It's really a serious problem, but I think at the present people are jumping on the wagon because they have nothing better to do . . . and I think the same of women's liberation." Another was asked what she saw herself doing 20 years hence: in an open acknowledgment of "male chauvinism," she replied, "Living in New York or Paris . . . married, with two children . . . a free-lance architect . . . [and married to] someone with a formal education . . . through college at least . . . a male chauvinist who would let me work at home as long as I take care of the house and kids."

In addition to their relatively greater concern for blackness than for their role as women or "liberationists," these students generally were not overtly struggling with questions about the style of life they wanted to lead or with religious or philosophical issues. Major discussions centering around career choice were not found in the interviews of the black students as they were in many of the white students' interviews. In addition, the black students did not tend to define their primary goal in college as "vocational," as did many of the black students entering college in 1966 who were studied by Hedegard and Brown (5). The interviews with black students, when compared to those with white students, contained less reflection about the most appropriate role for a young intellectual in contemporary society and about the difficulty in formulating a consistent philosophy of life

TABLE 1
Comparison of Mother's and Father's Occupational Status for Black and White Students

Relative Occupational Status of Mother*	Black Students (N = 32)	White Students (N = 42)
Greater than father's	8	1
Equal to father's	9	13
Less than father's	15	28

*Occupations were ranked according to the seven positions on the modified scale used to calculate the occupational status for Hollingshead's Two-Factor Index of Social Position (6).

when many of the major premises on which much of their parents' lives were based were being queried.

In some ways it seemed, in fact, that the black students were made so acutely aware of their blackness that it could not help but be a major issue in their lives, for others would not have it less. One black woman, asked whether black students were confronted with any particular problems at Yale, stated that indeed they were:

> But it is hard to articulate them. That's all people talk about and some of the reasons given for problems with black students I don't agree with. Black students are more pressed by their peers to conform to a certain type. It is all outlined and you have no choice. Some teachers just love "niggers" and some grad students . . . very liberal students . . . who have read all the books on blacks. If you're not like they think you should be, you're a "Tom" or "white." And there are black students who want you to be like them. They go on like "you owe it to us, you're black and we're black." It's hard to be yourself.

She continued to elaborate on how many black students had never been in a predominantly white setting before and therefore did not "know how to act." She also spoke of classroom pressures: "If you're a black student, you don't speak for yourself but for all black students and what they are."

OCCUPATIONAL STATUS OF PARENTS

These vignettes and others too numerous to recount document the concern among these students with black issues, but they do not explain the absence of references to concern with their oppression as women. For a possible explanation of this we must look beyond their days at Yale to what they told us about their homelife. When one closely examines the childhood experiences of these young people, one finds that most of the white male and female students come from families in which there is a clear disparity between the occupational status of their fathers and mothers. While both parents may be seen as intelligent, sensitive, and well educated, the father clearly has attained a greater occupational status than the mother. Frequently their fathers are businessmen, lawyers, academicians, or physicians; their mothers often do not work outside the home, and if they do, they are usually employed in such traditional female positions as social workers, teachers, and nurses.

This disparity in occupational status and/or academic achievement is highlighted again and again. One student's father was described as:

> The son of Jewish Russian immigrants. They lived in Philadelphia and were very poor . . . and he had to work. He's probably the brightest person I know. I make the distinction because I don't think he's only smart. He went to high school there and then to Princeton and graduated Phi Beta Kappa and magna cum laude. He got an M.A. and Ph.D. in history at Harvard. He planned to teach history but then went to B.U. law school and now is a lawyer.

The same student's mother was described as: "From an upper-middle-class Jewish background. She went to Smith and back to Sarah Lawrence for teaching credits."

Although not all discrepancies in education are quite so remarkable, other students alluded to analogous situations. One coed whose father was an engineer-turned-teacher said, "My mother didn't go to college, but is going now. But without a college education she is one of the most brilliant people I have met."

Some white coeds seemed to associate certain types of achievement with their fathers. One girl, whose father had attended a prestigious college and had gone on to be a Rhodes Scholar at Oxford and whose mother had switched colleges to be with her future husband, reflected: "Part of my problem is that I am probably more like my mother . . . but I have certain traits of my father, too. My parents are very different, yet they come off quite well. My father is more practical and scientific; my mother is flamboyant."

Such perceptions of mothers as "flamboyant" or less practical than fathers were generally not found in interviews with black students, nor was there such a discrepancy in occupational status ($\chi^2 = 8.70$, $p < .025$) (see table 1).

In black families the occupational status of the mothers is not infrequently on a par with or greater than that of her husband. Mothers often work as teachers, nurses, and office clerks, while fathers frequently are mail carriers or servicemen or hold positions of comparable status. One black girl who never knew her laborer father, but whose mother holds a master's degree, described her parents thus:

> My mother and father were divorced when I was very small, and I grew up with mom and grandmom. Mother knows what she wants and how to get it; I admire her determination . . . the fact that she is a strong person. I have the feeling she would do anything for her kids if she had to. She is unselfish when it comes to us. My stepfather has been married to mom for ten years. I really don't know him; I never wanted to know him. He's not interested in other people. Mom is a social worker. She got her bachelor's degree from Howard and her master's degree from Atlanta University. My stepfather is a mail carrier who went to school in Memphis and had no college. My real father and mother divorced when I was two. He also grew up in Memphis.

Regardless of the relative status of their parents' occu-

pations, the black students usually described their mothers in terms suggesting a more practical and less flamboyant status than did their white counterparts. One whose father was a physician and whose mother was a social worker described her father as "very quiet ... fairly easygoing but underneath always thinking ... he's not one to initiate an argument ... not heavy-handed. He loves his kids and out-of-doors. Inwardly my father has many aspirations for me because my brother didn't finish college and my father is hurt."

But she described her mother as "very dominant and outwardly strong ... she can't hold anything in. She has fantastic wishes and hopes for both her kids ... she's dominant!"

Another student, whose parents had not lived together since she was six years old, had a father who was a mail carrier and a mother who was employed as an executive secretary. Her description of her parents was nearly the reverse of that given by the girl whose father had been a Rhodes Scholar:

> My father is really intelligent but also uneducated. He gives me all the luxury items; my mother gives me all the necessities. My mother paid for private school. I'm like my mother in my academic orientation. And I'm easygoing like my father ... money is a thing to spend. My mother has a bachelor's degree and further credits; my father finished fourth or fifth grade.

SOCIAL STATUS OF PARENTS

Although there were some families in which a black woman's father was a professional and her mother a housewife, we encountered this much less frequently than among the white coeds. In fact, not only was there a significant difference between the relative occupational status of black and white students' parents, but, in addition, if the social class of the fathers and those mothers who are employed is calculated, one discovers by comparison a statistically significant difference in the distribution in the two groups ($\chi^2=7.13$, $p<.05$) (see table 2). Black students' mothers, more frequently than their white counterparts', hold occupations of greater status than those of their husbands. Also, and not surprisingly, when calculating their social class (which combines both education and occupation), we find that they occupy positions that are more often equal to or greater than those of their husbands.

Is it any wonder, then, that the black coeds were less concerned with being emancipated from subservient occupations when they grew up in a culture in which the female identity models and predominant social ethic were such that a woman would work and, moreover, work in occupations with status, in the eyes of the black subculture (or white subculture for that matter), equal to or greater than their husbands'? It cannot be definitely stated from this study that roots of such female achievement lie in the fact that black women sought careers such as teaching to give them economic freedom and protection from the sexual exploitation that they might have suffered as domestics for whites, as Grier and Cobbs (7) have suggested. However, our study does confirm their observation that black women have sought careers in such areas.

TABLE 2

Comparison of Mother's and Father's Social Class for Black and White Students

Social Class of Mother*	Black Students (N = 24)	White Students (N = 28)
Greater than father's	9	2
Equal to father's	7	12
Less than father's	8	14

*Social class was measured by Hollingshead's Two-Factor Index of Social Position (6), in which occupation and number of years of school completed are scored on the appropriate occupational and educational scales.

The stereotypical Jewish immigrant families often encouraged their sons to pursue careers in medicine or law for economic security in the New World. Unlike them, black families forced into a status somewhat resembling that of immigrants in the dominant white subculture have often encouraged their women, either overtly or covertly, to pursue careers that could afford economic security in their adult years in a society in which educational and employment opportunities were greater for black women than for black men.

DISCUSSION

Given, then, the fact that black female students are unlike their white counterparts, who as adults may be pursuing roles discordant with the predominant cultural ethic of their youth and in some ways antithetical to that of their predominant identity models (their mothers), one would anticipate that this would be less of a concern in adolescence and early adulthood for an intelligent black woman than her blackness. Most of these students are upwardly mobile and aspire to high-status occupations. Yet they cannot discount the fact that for years most of them grew up in a subculture predominantly consisting of people relegated by limited educational and occupational opportunities to a Class V or at best Class IV position. The same black female models who were on a par with their husbands occupationally were generally perceived as somewhat inferior by the predominant white subculture because of their blackness.

One could postulate—and, indeed, it would seem worthy of study—that blacks in some African nations who grew up in a predominantly black culture would be as unlikely to mention "blackness" in such interviews as whites are to mention "whiteness" or concerns for the "white community" or "white power." Furthermore, should such an all-black society be of a patriarchal nature with greater educational and occupational opportunities for men than for women and with a discrepancy between men and women in occupational status, as in the white American culture, one could postulate that some-

day in its history, too, cries of sexism would arise and a movement would form to liberate the women of that society.

Functions of the Lower-Class Partial Family

BY PAUL L. ADAMS, M.D.

Six million children in the United States experience the partial (fatherless) family. This type of family, which appears frequently in lower-class areas, somehow functions as a viable form. It is not a congenial structure for understanding by means of the classic psychoanalytic model or other "deficit" models. A "difference" model is proposed for understanding the lower-class partial family's functions regarding sexuality, economic life chances, authority, and honor. It is poverty combined with fatherlessness that accounts for the differences and, perhaps, the deficits.

PLANNERS AND POLICY MAKERS often look away, in every possible direction, from troubled families. Even revolutionaries who wish to push for a radical reconstruction of social institutions seem to have a preference for singling out economic and political institutions or educational institutions, as if the revolutions made by schoolmasters had been any more successful than other revolutions. The way that women and children live is accorded second place by most of the major theorists in the field of social policy. As a result, there have been few advocates of the rights of women and children or even of the welfare of familial units in which women and children are always the prime participants. Policy makers emphasize economic and political institutions, while making the assumption that the family stands (in some fashion or other) as an immutable structure that needs none of the guidance of the enlightened social engineer. My thesis is that family living might well be the focal point of the social planning of human services.

A truism holds that the basic biosocial unit is the nuclear family, consisting of a wife-mother, a husband-father, and their offspring. In one form or another the nuclear family, or perhaps more accurately termed the conjugal nuclear family, in which the husband-wife relationship is focal, is generally thought to be almost universal and irreducible as a kinship group. However, by 1960 only one-half of all families in the United States were composed of married couples who lived in a household with their own children (under age 18), without anybody else in the household (1). William J. Goode (2) has stated that the conjugal family contains a nuclear family, but with some added foci that place the conjugal family in an intermediate zone between a simple nuclear family and an extended family. The conjugal family (not the nuclear family) is the typical family form in industrial areas of the world, and most conjugal families are not as completely isolated from extended kinship ties to relatives-in-law and grandparents as would be called for by the strict nuclear family concept. In its pure form, therefore, the nuclear family certainly is *not* the universal family type in North America, even though it is the ideal type used as the conceptual model in most psychiatric discussions.

Urbanized and bureaucratized societies with prominent class divisions, such as the United States, exhibit a growing form of family that represents an incomplete or partial configuration of the conjugal family. In this type of family the mother-child relationship—not the husband-wife relationship—is the focal point. The partial family is characterized by the absence of a father as a permanent member of the household. It is a common form of broken family. It includes, in short, less than a conjugal nuclear family. It does include the mother and her offspring and perhaps some features of the extended

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Adams is Professor of Psychiatry and Director of Psychiatric Education, University of Miami School of Medicine, Miami, Fla. 33152.

family because of the presence of other relatives, notably the maternal grandmother. Also, affinal relations may be more vital and more extensive in partial families than in complete families.

This is the lower-class partial family (3) or the "denuded family" (4). It evidently possesses a remarkable durability in spite of its association with poverty and neglect. Worldwide, it is more common among members of the lowest income class than among people in other strata. It is the modality in which at least six million American children are being reared (5). It assuredly accomplishes some of the goals and purposes of the complete conjugal family. The partial family of the lower class deserves to be studied more fully as a viable form that functions for both individual persons and society.

COMPLETE AND PARTIAL FAMILIES COMPARED

The natural history of the complete conjugal family differs from that of the partial family. The former typically evolves out of the marital pair (sometimes called a truncated family), for that pair becomes a complete conjugal family only through the appearance of offspring. The truncated family (marriage pair) itself subserves important functions that vary from society to society and also among subsystems within a larger society. It is sexual activity that produces and distinguishes the conjugal family, and when the conjugal family is complete (not merely truncated or partial), it remains a structure promoting a high degree of sexual activity—particularly for adults.

The partial family, on the other hand, apparently develops by any of several distinct pathways.

1. It may develop unheralded, so to speak, when an unwed female gives birth to a baby whom she keeps and rears, without ever stably cohabiting with an adult male. More accurately, in the United States, it is often the maternal grandmother who rears this child.
2. The partial family may develop as a willful breakdown product whenever a conjugal family is rent by divorce, desertion, separation, or annulment.
3. It may emerge from the unwilled absence of one of the spouses. Death, imprisonment, military conscription, and economic catastrophes have all taken their toll from complete conjugal families in our epoch, converting them into partial families.

All three of these circumstances are most common among the lower classes; and it could be said that the manifest problems arising for partial families are, by and large, inseparable from the lower-class position of the family members.

Lower "classness" and familial "partialness" are mutually interacting functions in social pathology (6). Impoverished blacks in the United States exemplify the interaction of class and family form quite lucidly and directly. (I use lower-class blacks as an extreme example; obviously, all blacks are not poor and all poor blacks do not live in fatherless households.) Our racist society is so constructed that the family patterns of the blacks are conspicuous, creating especially for lower-class blacks a high prevalence of familial disorganization, dissolved marriages, and children born out of wedlock. Moynihan (7), whatever his biases, has documented the perilous statistical probabilities: One in four urban black marriages is dissolved; one in four of all black births is recorded as illegitimate.

Blacks, subjected to dual exploitation by racism and poverty, are the most mobile segment of the U.S. population. It is the old story, learned in slavery, of the disinherited being considered easily expendable, easily uprooted, and highly mobile, and then sometimes denounced as action oriented. The societal approach to their blackness, by compounding their poverty, compounds their movability and places the black family unit, because it is not as mobile as the black individual, at even greater risk. Individuals and family fragments are always more easily movable than complete conjugal families. Hence, it is intrinsic to our North American societal structure that it promotes the growth of the partial family among blacks and fosters their corresponding receipt of public welfare funds. This mode of societal production of cyclical neglect continues, however unsound a partial family might be from a sociopsychiatric standpoint (8) and regardless of the many researches that show that adequate family welfare systems can prevent and alleviate social pathology.

FUNCTIONS SUBSERVED BY THE PARTIAL FAMILY

Psychiatric consensus holds, by and large, that the partial family functions defectively in five respects: biologic maintenance, social control, enculturation of children and youth, status placement, and emotional maintenance. Although most births the world over are still classified as legitimate, it is only in reproduction that the partial family is held to function as effectively as the complete family, since marriage is not regarded as a prerequisite for procreation.

In spite of its being decried, the partial family does function. It does persist, and it is condoned by society. All these facts lend credence to the view that men who derogate it perhaps do so only because it is a family in which women are not ruled by men. A strong case could be made for the viewpoint that the partial family, *if it is not poor*, functions quite fully for everything that a complete family does—biologic maintenance, social control, enculturation of children, status placement, and emotional maintenance, as well as reproduction.

Many discussions of the partial family in the United States are highly charged with political sentiments (9). Some progressives who fear being anti-black place themselves in the ludicrous position of defending the partial family so fully that they end up praising it and contending that members of partial families do not need any special assistance. Conservatives, on the other hand, are in the position of arguing that the partial family is patently debased and inevitably pathologic, but they contend that it must not be coddled and that it warrants no

special assistance programs. Equally, then, neither the progressive nor the conservative described becomes an advocate for needy black families. Political neglect is an outgrowth of both ideologies.

SOME ACTUAL DIFFERENCES

A partial family does differ from a complete conjugal family in at least four important ways. It is sexually, economically, politically, and honorarily unlike the complete family unit. If these differences are, by comparison, also deficiencies, they are by no means insurmountable deficiencies.

Sexual Differences

A partial family is sexually different from a complete conjugal family. The latter requires a more or less durable relatedness between adult female, adult male, and child, whereas the partial family includes only one parent. Hence, by definition a stable conjugal relationship is missing. Sexual opportunity and sexual rights and responsibilities are all impaired or jeopardized in the partial family. In a "matrifocal" fatherless family the chances are lessened for children to establish their identities with respect to a valued father (10). Stated differently, the "matriarch" of a partial family might assertively disvalue males. She "puts down" the male, the penis, copulation, male lust, and all facets of maleness. Proponents of the familiar contend that the mother alone cannot train boys for their subsequent fatherhood (4, 11), and their contention is reinforced by every instance of partialness that is compounded by poverty. The forecast contains its own fulfillment vehicle. Also, it diminishes what mothers alone can teach about maleness and what children can learn on their own from adult males other than the father.

The hearing, seeing, touching, and smelling of sex differences are important ingredients of life for the young child. Not to know a sexually robust male as one's father is conceivably a crippling deprivation for one's psychic unfolding. Not to experience the daily wranglings and reconciliations of truly conjugal, interactive, and loving parents is a psychic deprivation for the child. It is depriving because the child might not learn roles essential to his own later procreative family life, i.e., to parenting, which is after all the goal of all child rearing. The family is, par excellence, the school for parenting in all economic classes, and in the lower-class partial family some skewed schooling for parental behavior occurs (12).

Economic Differences

A partial family is economically different from a complete family. In the fatherless family, the getting and the giving of security are thrown awry. Both the family's "expressive function," referred to by the phrase "feeling secure," and "instrumental function," often referred to as "biologic maintenance," are imperiled.

It is possible that there is a wide range of variations in the providing of material security within a family unit, but one thing is certain: Children always consume security, and parents provide it. Both parents may participate directly in work for pay, or only one parent may, as, for example, the middle-class father. Research in maternal deprivation has revealed that when a young infant's mother is away (at work or in the hospital or dead) during the period when the infant is six to 18 months old, serious emotional deprivation is most likely to occur, with far-reaching consequences for the child (13). Since infants need to derive security from mothering persons, poverty is the economic substrate for maternal deprivation.

Even in poverty the conjugal family has economic advantages surpassing those offered by the partial family. Despite his being unemployed and having his leadership eroded, as Mirra Komarovsky (14) has shown, the father, being present, is an asset to family morale by virtue of his presence as an employable adult male. Some property, skills, technology, and economic potential accrue whenever a father is present in a household. As a corollary, whenever a female adult is the sole parent present in the urban slum family, the children are thus lacking in security. In this case, money (in the form of a family subsidy, guaranteed annual wage, and negative income tax) would assist the poor to strengthen their family life and would alleviate some of the most serious problems of the lower-class partial family. Leon Keyserling and Barry Goldwater have acknowledged this need, as have many people whose politics lie somewhere between Goldwater's and Keyserling's. Poor people do need money.

Political Differences

A partial family is politically different from a complete family. The allocation of authority, both formal and informal, seems to handicap the child who grows up in a partial family. Whether the family is patriarchal, matriarchal, "filiarchal," or egalitarian, the give-and-take and checks and balances of family living instill in the child of the complete family a "political sense" that serves him advantageously in the larger modern society where much hammering out of power arrangements is required.

The child in the partial family learns little of all those power relations which are in the paternal mode. I was intrigued many years ago when one of the black college students in a class I taught said to another, "Oh, good, I had heard it was your mama that died. I didn't realize it was just your daddy." That condolence bespeaks matriarchy, without a doubt; but matriarchy is a form of family and of human experience that has durability and merit. Furthermore, a true matriarchate is a complete family—a unit of male, female, and child or children. Perhaps it is not matriarchy that must be diminished, but only the impoverished partial family. Erstwhile poor families (whether they be black or white) are bound to show vestiges of matriarchy that persist for two or three generations, despite any upward mobility that they may experience. I see no reason why the poor family must be required to become like the affluent, or the blacks like the whites. Service programs for children who are in need

certainly do not require that uniform family patterns must first be established before help is extended to the children.

Honorary Differences

A partial family is honorarily different from a complete family. Generally, the child with least shame and least apology comes from an intact conjugal family. His reputation and self-esteem are more firmly guaranteed. On the other hand, the child from a partial family must move about constantly feeling derogated and ill at ease.

Psychodynamic investigation has demonstrated that, in the main, the outlines of a child's self-concept are laid down in the first two years of life. Nonetheless, the continuous reinforcement of unfavorable (or favorable) self-pictures operates to revalidate one's image during all the subsequent years of life. Children in all eras undoubtedly have felt excruciating shame for their parents (15), most notably when their parents have not been "respectable" in the community. Blacks are often found to be riddled with self-hate (16). Blacks living in slums project this onto a humanity that is vicious and evil, not always realizing that their very self-hatred is a manifestation of their oppression by racism and poverty.

When in a white, racist world the darker black child is derogated by his own black mother, when the fact of blackness is regarded as an ineradicable stigma, and when black families perpetuate racism both directly (as "White is best") and in its reversed form as black racism ("Black is best"), then the black child wrests self-esteem at a high cost. If, in addition to being black, he is poor and has no father, he and his self-respect could be said to have "had it" three ways!

CONCLUSIONS

It seems important to recall that not all poverty is equally disorganizing or anomic (17). In many poor families there prevails a sense of integrity, humanism, and competence—with the invariable accrual of edification to all members of these families. However, these are infrequent individual cases, and although they defiantly transcend the norm, they cannot be made the focus for generic social engineering. The latter requires a closer look at the statistical norm. The norm is more informative and more relevant. To the extent that the lower-class partial family is the norm, it—not the successful exceptions—must be underscored as the focus for initiating change. If the lower-class partial family does perform necessary social functions, then it merits subsidy and supporting services so that, at least, it can function under reduced economic burdens.

About Psychiatry, Psychiatrists, and Social Problems

IN PUBLISHING THE GROUP OF PAPERS that appears in this month's Special Section, the *Journal* is facilitating a process that is of major importance for psychiatry and for psychiatrists: that of evolving "a consensus about the place of social and community psychiatry in our profession" (1).

Pursuit of such an objective—in itself a social issue—involves changes in our concepts and practices, and thus, as with change process in general, it engenders transitional confusion, conflicts, and turmoil.

One approach to the study and resolution of problems that psychiatrists have customarily used to advantage is that of a case method. This can be applied not only to clinical cases but also to nonclinical case situations. Thus, the six papers in this section may be read not only with regard to their respective topics per se, but also as "cases" of social psychiatry. Each reader is thereby provided with examples of how these particular authors have variously related social and psychological data to psychiatry. It would seem decidedly helpful to examine critically each such case example from the standpoint of furthering one's thinking through of key problematic questions about social psychiatry. For though it is easier to generalize and to take stands about these questions in the abstract, it is when we get down to specifics that we confront their true complexity and their implications for psychiatry and psychiatrists.

Some of the pressing questions and dilemmas that beset us, and upon which controversy centers, stem from the rapid expansion of our professional domain that the developments in social and community psychiatry have been bringing about. Thus, for instance, are we exceeding the limits of our professional knowledge base and competence by involving ourselves in problems such as racism, poverty, war? Or, if we avoid such involvement, are we failing in our rightful professional responsibilities? Furthermore, although these broad issues are of critical importance to us all as citizens, are they relevant to our central psychiatric mission with regard to mental illness? Can we as physicians preserve our essential objectivity if we become active in political controversies in our professional capacities?

In addressing themselves to these questions, an increasing proportion of APA members in the past few years have signified their commitment to extending and intensifying the profession's involvement in broad social problems as these relate to mental health and illness.

The term "involvement," however, means many things to many people, and individual psychiatrists vary, of course, in how each is equipped and motivated to express it in his particular work. But for our profession as a whole, responsible involvement in social issues must encompass a synergistic aggregate of different kinds of psychiatric effort.

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

Thus, the soundness and value of our pronouncements and positions on matters of broad public policy depend on the results of scientific investigation and scholarship, as well as on clinical understanding and experience. But the social utility of findings about sociopsychiatric relationships depends on our making these known to the policy makers and to the general public, and in our combating, through political process, those features of society which pose serious threats to mental health.

While to some of us, activity in politics seems at variance with the physician's role, it can be recognized as consistent with it *if* it is used as an indirect tool for the traditional psychiatric purpose in preventing and relieving mental disorder.

By definition, the hybrid term "social psychiatry" connotes the necessity for cross-disciplinary collaboration, as well as for many other new types of working relationships and work settings. Previous unfamiliarity with these and many other aspects of social psychiatry can be anxiety arousing and thus complicate one's attitudes about its value. For both adherents and opponents of greater social involvement of psychiatry, the personal emotions and conflicts that are entailed warrant the professional safeguard of our careful and continuous self-examination as we strive to integrate clinical and societal approaches for greater psychiatric effectiveness.

VIOLA W. BERNARD, M.D.

Dr. Bernard was formerly Director, Division of Community and Social Psychiatry, College of Physicians and Surgeons, Columbia University, New York City.

More Changes for the *Journal*

THE ARRIVAL of the January 1973 issue of the *Journal* in its new "A" size, and with its new cover and changes inside, probably startled some of our readers. We had written about these changes earlier, but the actualization might have been a little more dramatic than we anticipated. Also, the January issue began volume 130: henceforth our volumes will run concomitantly with the calendar year. None of these changes came easily. Like most of our readers, we had gotten quite comfortable with our green journal. However, technological progress propelled us in the directions we took, and we cannot look back nostalgically now. We noted earlier that change, while ever necessary, is often painful.

We now have another announcement. On December 8 the Board of Trustees approved changes in the makeup of the Editorial Board, as three distinguished colleagues rotated off and three new ones were appointed. Those who are leaving the Board are Doctors Henry Brosin, Henry Davidson, and Howard Rome—distinguished associates, all of them; the last mentioned is president of the World Psychiatric Association. They have been valued associates and have done excellent work, and all of the official *Journal* family regret that they are leaving. Their departure is made easier, however, by the fact that they have promised to continue to help when called upon. The *Journal* and the APA owe this trio deep and sincere thanks.

New members of the Editorial Board are selected according to the needs of the *Journal*, the expertise of the individual in certain aspects of our discipline, and by their

records of assistance above and beyond the call of duty in reviewing manuscripts and books. True enough, there are many colleagues who meet these requirements, and the Editorial Board was hard put to make final recommendations to the Editor. Basically, the deciding factor was the *Journal*'s urgent need for expert assistance, particularly now as our office is inundated with manuscripts and our specialty becomes increasingly complex.

The Board of Trustees has approved the following appointments; this month their names appear on the masthead of the *Journal* for the first time:

John M. Davis, M.D., former Chief of the Unit on Clinical Pharmacology, Laboratory of Clinical Science, National Institute of Mental Health, and former Associate Professor of Psychiatry, Johns Hopkins School of Medicine. At present Dr. Davis is Professor of Psychiatry and Associate Professor of Pharmacology, Vanderbilt University School of Medicine, Nashville, Tenn., and Director of the Clinical Division, Tennessee Neuropsychiatric Institute. He is consultant to a number of government agencies and since his graduation from Yale Medical School, where he won the research prize in 1960, he has written or been co-author of nearly 200 scientific articles. It is known in the *Journal* office that when Dr. Davis reviews a manuscript, the staff receives a liberal education from his comments.

Dr. H. Keith H. Brodie is at present Assistant Professor, Department of Psychiatry, Stanford University School of Medicine, Stanford, Calif. He has been the recipient of numerous awards and fellowships, among them the Sol Ginsburg Fellowship of the Group for the Advancement of Psychiatry, the A.E. Bennett Clinical Research Award of the Society of Biological Psychiatry, and the Psychopharmacology Award (first prize), American Psychological Association, 1970. Dr. Brodie is Special Assistant to the Chairman for Administration, Department of Psychiatry, Stanford University, and is Chairman of the Medical School Faculty Senate. He has held several visiting lectureships and has been closely associated with Dr. Melvin Sabshin on the Program Committee of the APA; he currently serves as vice-chairman of that committee.

Dr. Rebecca Solomon has been Senior Clinical Associate in the Department of Psychiatry at Yale since 1968. She had graduated from that institution in 1939 and was an intern, a Milbank Fellow in Medicine, and later a resident in psychiatry in the same institution. Dr. Solomon is also a graduate of the Western New England Institute for Psychoanalysis (1960), and since then has served as its vice-president and is now its president. She has also been the president of the Connecticut Psychiatric Society and has been the recipient of many honors. Dr. Solomon's experience has been broad. She has been a member of the Connecticut State Board of Mental Health, a representative to the Executive Council of the American Psychoanalytic Association, and a lecturer at the University of Connecticut School of Social Work. Earlier in her career she was psychiatrist and physician to the Connecticut School for Boys. At present Dr. Solomon teaches at the Institute of Living, Hartford, Conn., and at Yale Medical School and is in the private practice of psychiatry in Hartford.

The Editorial Board and the staff welcome these new members of the Board and look forward to working with them. Their capabilities have already been proven, their expertise is needed, none of them is a stranger to hard work, and their duties on the *Journal* Board will keep them in practice.

F.J.B.

BRIEF COMMUNICATIONS

Countertransference Reactions to Violent Patients

BY JOHN R. LION, M.D., AND STEFAN A. PASTERNAK, M.D.

Treating violent patients can evoke countertransference reactions of fear and anger in therapists that may interfere with effective management. The authors present six case reports in which countertransference reactions deleteriously affected the treatment outcome. They stress the importance of the physician's being aware of his fear and of how this fear may distort, by projection, his view of the patient as being dangerous.

IN PREVIOUS WORK we have described the clinical features of patients who appear in emergency room and clinic settings with complaints relating to assaultive and destructive urges (1–4). In the course of treating and supervising the therapy of such patients, we have noted recurring countertransference reactions that interfere with their evaluation and management. We describe here the nature of these reactions, using the term "countertransference" to mean any emotional reaction that the clinician has toward the patient (5).

Probably no group of patients evoke as many anxieties in the clinician as those who relate such violent urges as the fear of running amok and of killing someone or those who describe patricidal or infanticidal impulses. While the suicidal patient's aggressive urges have not yet transcended his personal boundaries, the violent patient—particularly if he has been violent in the past—is an individual who may hurt someone besides himself. In the back of the clinician's mind is the possibility that the patient may turn his aggressive urges on his therapist if the latter does not fulfill the patient's therapeutic expectations. The clinician may also fear that his patient will develop a pathological distortion of therapy; stories about the paranoid patient who kills his psychiatrist are commonly fantasized.

It is therapeutic wisdom for the therapist to have some anxiety about treating a violent patient. In the case of a paranoid patient, for example, concern for the development of a dangerous psychotic transference should continuously propel the therapist to carefully monitor the relationship with the patient. However, while hazards exist in treating the violent patient, we have observed that anxiety concerning the patient's dangerousness often gets out of hand.

Dr. Lion is Assistant Professor and Director, Clinical Research Program for Violent Behavior, Institute of Psychiatry and Human Behavior, University of Maryland School of Medicine, 645 W. Redwood St., Baltimore, Md. 21201. Dr. Pasternak is Assistant Professor and Director, Outpatient Clinic, Department of Psychiatry, Georgetown University School of Medicine, Washington, D.C.

CASE REPORTS

Case 1. A prisoner convicted of assault was transferred to the psychiatric unit of a hospital because of suspicious behavior. He was evaluated by a staff psychiatrist, who found that he was not psychotic but that he did have definite paranoid traits. The patient blamed all of his difficulties on the police and prison authorities. He was negativistic and hostile and spoke of physical force as a solution to emotional problems. Interviews with him were difficult, and his psychiatrist emerged from a particularly frustrating session with marked anxiety and an irrational fear that the patient, who still had a one-year sentence to serve, would try to ambush him at home and kill him. In a discussion with a colleague he came to the realization that he was furious at the patient and actually had the desire to physically strike him. As he came to grips with these feelings, the fear of harm subsided, and eventually a more positive relationship prevailed during the remainder of treatment.

In this case the therapist did not have easy access to his angry feelings and became irritated because the patient continually projected all of his difficulties onto the environment and evaded introspection. This is particularly likely to be the case with paranoid patients. Patients who act out extensively, such as those with severe character disorders, also produce the same feelings in physicians. Although the acting out may be dynamically understood by the physician, he may still feel anger and helplessness in controlling an individual who translates affective issues into destructive behavior—behavior that the therapist may feel reflects badly on his therapeutic abilities. Anger and helplessness seem to us to be the basis for another not-uncommon fantasy expressed by therapists: that their patients will do something terrible (e.g., commit a mass murder) and that they, the therapists, will then be held liable. Such fantasies, of course, always require the most serious and urgent consideration as to their basis in fact. Yet we have observed that this particular fantasy often derives from a feeling of anger and helplessness which the physician has toward his patient. This helplessness is projected onto the patient, and he is perceived as an individ-

ual capable of doing immense harm. In case report 1, anger led to the physician's fearing personal harm even though no threat had been made.

Helplessness may also be evoked in the physician by the fact that the patient is potentially dangerous. This helplessness is apt to be handled defensively, as the following case report illustrates.

Case 2. A 36-year-old man was admitted to the hospital in a state of delirium tremens and was treated by a first-year resident psychiatrist. As he improved, he was allowed a special pass to leave the hospital. He returned from leave one night with a loaded revolver.

Apparently he had brought back a bulky package and had handed it in with his other personal belongings. When the package was submitted to routine inspection, the weapon was discovered. The patient readily admitted that it was his gun and that he had brought it to the hospital for "safe keeping." The resident hastened to the ward to discharge the patient because "those who bring guns to the hospital obviously do not belong here." He resisted understanding the meaning of the man's behavior. He ignored the fact that the patient could have kept the weapon concealed and that his turning it in to the hospital reflected an underlying conflict.

When instructed by staff supervisors to retain the patient in order to further investigate this conflict, the resident refused. He persisted in his wish "to be rid of the derelict." Only the threat of suspension made the resident alter his stance. It was subsequently learned that only six weeks before the man had been released from prison because of armed robbery. He had been approached by his friends to take part in a new holdup but had turned his weapon in to the hospital, hoping for protection. In discussion it became evident that the resident harbored a marked fear of the patient and of weapons. His insistence upon discharge was his means of dealing with his anxieties.

This case illustrates the physician's overreaction to the violent patient and the principle of denial. Denial is the most ubiquitous defense against anxiety generated by a violent patient. In its most common and most insidious form, it manifests itself in the clinician's failure to gather unflattering and anxiety-producing anamnestic data. Time and time again we have found it necessary to ask residents to inquire about patients' ownership of weapons and ammunition, their lethal skills, past criminal or violent acts, or driving habits. It has been our distinct impression that psychiatrists do not ask such questions, but defensively conceive of these queries as belonging more in the forensic realm than in the province of clinical psychiatry. The need to ask such questions has been stressed by Macdonald (6). In certain other instances the predominant emotional reaction to the violent patient has been anger or rejection of the patient as a "prison case," an "untreatable psychopath," or a "harmless drunk"—this despite the knowledge that drinking is implicated in a very large proportion of violent crimes and automobile fatalities.

The following case report is an interesting, although extreme, case of denial.

Case 3. A 19-year-old college student barged into the office of his therapist armed with a .22 rifle. He fired, but the gun failed to discharge, and the student attempted to strangle his would-be victim. The therapist fought back enough to discourage his patient, who then wept. The patient called out for help and protested that once again he was the victim of racist plots that might destroy him. He begged for mercy. The therapist took the gun and gave it to his secretary. He then escorted the tall, heavy-set patient to the emergency room—a long walk over the hospital grounds and through a complex series of dark tunnels. Once there, he notified the emergency room clerk to summon the psychiatrist on call, since he wished to admit the patient to the hospital. He gave the clerk no information regarding the urgency of the request. The doctor then left the patient sitting alone in a room. Two hours later the psychiatrist on duty, who had still not been notified about the case, found the patient. The referring psychiatrist explained his approach, saying: "I did not want to influence your decision regarding the need to admit the patient."

This is a frightening case and an unusual one. The denial can well be understood in the face of the crisis but is nonetheless glaring. An additional interesting fact about this case was that in therapy the resident overlooked the dangerous potential of the patient and focused instead on his earlier life conflicts, his mistreatment at the hands of cold and controlling parents, and his difficulties facing the vicissitudes of life. He avoided dealing with the negative aspect of the patient's psychotic ambivalence and hostilities until, at length, this omission was pointed out to him in supervision. Both the resident and his supervising therapist had made extreme attempts to form a positive therapeutic alliance with a patient they sensed to be dangerous.

To face the issue of dangerousness is very threatening to the physician, much as it is to face the seductiveness of a female patient; the therapist's human vulnerability emerges, and he must deal with his own strong emotions. Aggression is a subject that revives conflicts which the psychiatrist is apt to have about his own urges. It has long been our opinion that the psychiatrist is in closer dynamic harmony with suicide and the introjection of hostile urges than he is with the externalization of such impulses. Violence directed outwardly is apt to be threatening. Events in the physician's life may be stirred up, as the next case report illustrates.

Case 4. A hospital staff psychiatrist sought informal consultation because he was afraid of a patient. The patient, who had a severe character disorder, had difficulty with hostile urges and had verbalized a desire to shoot another person. The psychiatrist, although never theatened, expressed fears for his own safety. In the course of conversation the psychiatrist related that several weeks before, he had gone on a camping trip with his wife in the mountains. The couple stopped to look at the scenery. Another car drove up, and a man got out and engaged in conversation. He then abruptly drew a revolver, fired at the psychiatrist at point-blank range, but missed. The psychiatrist instinctively tackled the man, throwing him over a ledge. The couple then immediately raced off, encountering a state trooper who ordered an immediate search of the area. The man was eventually found; he had a broken limb and was discovered to be an escaped prisoner.

This case demonstrates the revival of an actual, past attempt on the physician's life; this memory led to a distortion of the patient's dangerousness and interfered with

a working relationship. In other cases we felt that the patient's patricidal or infanticidal impulses reawakened conflicts that the clinician himself had about similar impulses. This seemed to be the case when the therapist had ruminative, obsessive preoccupations about the dangerousness of the patient. Our speculation was, of course, difficult to prove in the course of supervision, since personal exploration is inappropriate in such settings. Ventilation, however, proved to be immensely useful and led to a more realistic appraisal of the patient. Fromm-Reichmann (7) has described a personal case in which she was irrationally afraid of a patient; consultation led to a therapeutic relationship unhampered by such emotions.

Patients on ward settings can generate negative countertransference reactions among nursing personnel (8). This happens most typically when the patient is agitated and exhibits motor restlessness or belligerence, together with flouting of ward rules and regulations; as a result, nursing staff members become alarmed and angry.

Case 5. A 19-year-old college student with a long history of drug abuse was readmitted to the hospital in a state of toxic psychosis. He was unkempt, incoherent, agitated, and menacing. A well-developed, muscular young man, he acted bizarrely and unpredictably reached out for those who passed by him. During patient group meetings, he would pace nervously and suddenly thrust his face close to the face of another. At times he shouted wildly and refused to obey instructions. He talked of wishing to kill his father for being "a bastard." The patients decided to exclude him from the group meeting. Staff members reacted to the fears of the patients and gave the patient increasing amounts of medication. The patient was also placed in seclusion where he became violent and banged on the walls. This behavior generated even more anxiety, and more repressive measures were taken.

In viewing the situation with ward personnel, it became apparent that the patient had responded to verbal intercession in the past, although persistent efforts were indeed required in this direction. Because of frustration and fear, necessary attempts to talk with the patient had been abruptly abandoned in favor of sedation and isolation. When attempts were again made to talk with the patient about his anger, he responded positively, and the other measures were not needed.

This case points out how a patient's dangerousness can become exaggerated by the very measures that are prematurely instituted to control him. The staff members withdrew from interacting with the patient and handled him punitively. This intensified a bad situation, since it removed the patient from therapeutic human contact and worsened his alienation. Since patients with aggressive urges fear losing control of such urges, they become even more agitated when they sense that everyone is afraid of them. In the situation described here, ventilation of the staff members' frustration with and fear of the patient led to a reduction in their perception of him as threatening.

Identification with an aggressive patient can occur in ward settings.

Case 6. A 26-year-old soldier was hospitalized because of bizarre, violent behavior. It was learned that he was a former boxer and professional football player, with a long record of violent outbursts for which he had been hospitalized. He was a powerfully built man who projected an aura of dangerousness. His arrival on the ward caused great concern among the staff. All of them wished to know what to do in case he "went wild," since they feared that no one could restrain him.

Within several days an interesting reaction was noticed. Some nursing staff members began to supply him with cigars; several of the patients and staff members began to imitate his mannerisms, and his colloquialisms became widespread among certain male patients. Weight lifting became a fad on the ward, and a number of younger staff members and patients were soon participating in physical exercises with this patient, who regularly performed his own. Within several weeks the patient was elected to a leading ward government position. These events had a beneficial effect on the patient, who seemed transformed into a well-liked individual.

One night, however, when aroused from bed by a policeman who had come to investigate a recent act of violence, the patient became enraged and threatened to kill "the goddamn cop." He was on the verge of losing control and of violently attacking his accuser when patients and staff approached him and assiduously encouraged him to contain himself. He ranted and raved and broke a chair but did not attack his accuser. This explosive incident exposed his deep-seated problems and his barely submerged potential for violence, issues that had not come to light until then.

More subtle variations of identification are occasionally noted on ward settings. Staff and patients, as well, may take a special interest in the patient, find him "charming" or "interesting," and listen avidly to his accounts of past antisocial acts without coming to grips with and challenging the patient's aggressive propensities.

Patients who experience violent impulses desperately want help in curbing such urges (2, 3). Violent patients are terrified of losing control and welcome therapeutic efforts that restore a sense of control and prevent them from acting on their urges. To this extent the therapist must explore all avenues of aggression with the patient and squarely face issues of destructiveness, pointing out to the patient that the goal of this exploration is to prevent the very aggression that disturbs him. The physician must be aware of his own fear of and anger at the patient and of the effect these feelings may have in distorting the dangerousness of the patient via projection. The therapist must be careful not to reject the patient or to forget to inquire about situations that could result in the patient's becoming violent. Finally, the clinician must be aware of the emotions evoked in nursing staff by violent patients and the role these emotions play in complicating management of an already problematic group of individuals.

Imipramine Therapy and Seizures: Three Children Treated for Hyperactive Behavior Disorders

BY DAVID BROWN, M.D., BERTRAND G. WINSBERG, M.D., IRV BIALER, PH.D., AND MARK PRESS, M.S.

The authors report three cases of children who developed seizures while receiving imipramine treatment for hyperactive-aggressive behavior disorders; all three children had organic brain disease but no previous history of seizures. Two of the children remained seizure-free after anticonvulsant medication was added to the imipramine regimen. The authors suggest that clinicians prescribing imipramine be alert to the possible complication of seizures.

RECENTLY we reported imipramine to be effective in the management of behaviorally deviant children (1). While we found imipramine to be beneficial, we cautioned that its use required close surveillance for possible systemic toxicity. Since the preparation of that report, we have observed the development of seizures concomitant with imipramine therapy in three children without a previous history of a convulsive disorder. This paper reports those cases.

CASE REPORTS

Case 1. D.A. was a three-and-one-half-year-old black male who was seen in the neurology clinic for evaluation and treatment of hyperactivity and autistic behavior. History indicated he was the product of a normal pregnancy, labor, and delivery and weighed five pounds, eight and one-half ounces at birth after a 40-week gestation. Normal development was manifested up to one and a half years of age. From ages one and a half to three and a half, retarded progression was characterized by babbling, lack of understandable language, failure in toilet training, and inability to play with toys or to relate to people in a conventional manner.

There was no past medical history of meningitis, encephalitis, pica, serious head trauma, or convulsions. Both parents and all siblings were alive and well. There was no family history of seizure disorders.

Physical examination revealed a tense, irritable, hyperactive boy who related inappropriately to adults—running around the room, babbling, and screaming. He was below the third percentile in weight and below the 25th percentile in height. The standard physical and clinical neurological examinations were negative. The Gesell Developmental Neurological Examination revealed an adaptive developmental quotient of 70, with considerable scatter on all subtests. This is consistent with a diagnosis of chronic organic brain disease and retarded intellectual development.

Skeletal survey, 12 laboratory determinations of blood chemistry, dermatoglyphics, and blood count were normal. Electroencephalograms performed at three months prior to, one month prior to, and two months after the seizure episodes were interpreted as normal for age-sedated sleep.

D.A. was initially treated with 5 mg. of dextroamphetamine twice a day and was subsequently switched to 10 mg. of methylphenidate daily. Since both medications resulted in increased hyperactivity, 25 mg. of imipramine three times a day was instituted, and improvement was noted. Because of the development of tolerance after three weeks, the dosage was increased to 25 mg. four times a day, then to 50 mg. three times a day. After receiving 50 mg. three times a day for one week, he developed intermittent tremors, which did not disappear in sleep and which were followed by two seizure episodes one week later. The first episode consisted of falling from a chair and vomiting, followed by a two-hour period of lethargy and hypotonia. The second seizure occurred three hours after the first and was character-

At the time this paper was written Dr. Brown was a medical student at Downstate Medical Center, Brooklyn, N.Y.; he is currently an intern at Long Island Jewish Hospital, New Hyde Park, N.Y. Drs. Address reprint requests to Dr. Winsberg at the Child Psychiatric Research Center.

The authors would like to thank Kytja Voeller, M.D., who read and interpreted the EEGs.

ized by clonic tonic movement of the extremities, followed by postictal sleep. Neurological examination, skull X rays, and blood count performed at periods of four hours and one week after the convulsions were all within normal limits.

Medication was subsequently discontinued with no further evidence of seizure disorder for a six-month period (i.e., to the time of this writing).

Case 2. G.R. was a six-year-old black male admitted to the psychiatric unit for control of hyperactive and aggressive behavior. His mother had had a normal pregnancy, labor, and delivery, and he weighed seven pounds, 14 ounces at term. He showed normal development up to one year of age, at which time he was hospitalized for tuberculous meningitis. Subsequent retarded development has led to a current Merrill-Palmer IQ of 52 and a full scale IQ of 53 on the Wechsler Preschool and Primary Scale of Intelligence.

G.R. was again hospitalized at age two for pneumonia and at age six for a tibial fracture. He had no history of serious head trauma, pica, or convulsions, and there was no family history of seizure disorders.

Physical examination revealed a hyperactive child who was above the 50th percentile for both height and weight. Both neurological and physical examinations were within normal limits.

The patient was treated with 50 mg. of imipramine three times a day for one week with good results, but the dosage was increased to 75 mg. three times a day to overcome tolerance. After three weeks on this regimen, he experienced a clonic tonic seizure with incontinence, drooling, and eye rolling, followed by 40 minutes of postictal sleep.

Neurological examination and electroencephalogram on the following day were within normal limits for age. He was continued on 75 mg. of imipramine three times a day, combined with 30 mg. of phenobarbital three times a day, with good control of behavior and no further seizures. Loss of behavior control five months later prompted changing medication to 50 mg. of chlorpromazine three times a day. He has had no recurrence of seizures during the 13 months prior to this writing.

Case 3. A.S., an eight-year-old black male, was seen in the clinic for evaluation and control of severe hyperactive and aggressive behavior. The mother's pregnancy, labor, and delivery were said to be normal. However, the child weighed four pounds at term after a 40-week gestation and required incubator care for one week. His development was characterized by relative physical inactivity for the first two years, first sitting unsupported at ten months and walking alone at 18 months. He remained enuretic until age eight.

Medical history included pyelonephritis at seven months of age and rubella at nine months. There was no history of serious head trauma, meningitis, pica, or convulsions. He was the fifth of seven children. One sister, age three, was retarded, and a brother, age eight, showed a severe behavior disorder.

Repeated physical, neurological, and laboratory examinations were all within normal limits. He was of average height and weight, with a Wechsler Intelligence Scale for Children (WISC) IQ in the dull-average range.

A pretreatment electroencephalogram (EEG) was interpreted to be "an abnormal tracing, no specific focus, nonparoxysmal, compatible with some form of cerebral dysfunction." After unsuccessful trials on dextroamphetamine, methylphenidate, trifluoperazine, and haloperidol, A.S. was treated with progressively increasing doses of imipramine up to 75 mg. three times a day, with good clinical response. However, after three months of treatment, he experienced a grand mal seizure that was preceded by tremors and characterized by an expiratory grunt, tonic clonic movements, and loss of consciousness. Subsequent examinations were normal, except for an EEG performed one day after the seizure; this was read as being "poorly organized, no clear epileptic abnormality."

Dosage was subsequently reduced to 50 mg. three times a day, with good behavior control until two months later. At that time the patient, who had been off medication for a period of five days, exhibited mutism, staring episodes, and purposeless, disorganized, and frenetic behavior, which prompted hospital admission. Physical, neurological, and laboratory examinations were noncontributory except for two EEGs. The first EEG was interpreted as "normal sleep pattern in an awake subject," and the second as "much paroxysmal slowing, consistent with encephalopathy." The patient improved on diphenylhydantoin (Dilantin) and was subsequently discharged, fully recovered, on a combination of 60 mg. of diphenylhydantoin three times a day and 50 mg. of imipramine three times a day. Laboratory data, including a lumbar puncture examined for viral disease, were negative.

Two months later A.S. was readmitted to the hospital after experiencing two grand mal seizures that were precipitated by an inadvertant decrease in the diphenylhydantoin dosage. An EEG performed two days after the seizure revealed "paroxysmal slowing and high voltage, compatible with grand mal seizures." The most recent EEG, performed one month later, was read as "abnormal record, poorly organized with biposterior paroxysmal slowing."

He has remained seizure-free to the time of this writing (a period of one and one-half months) on combined dosages of diphenylhydantoin and imipramine.

DISCUSSION

There have been several scattered reports in the literature associating imipramine treatment with the development of seizures in both depressed adults and enuretic children (2–6). On the other hand, it is interesting to note that Fromm and associates (7) found imipramine to have an anticonvulsant effect on minor motor and/or petit mal seizures in ten of 13 children with coexistent grand mal or psychomotor seizures. Unfortunately, they also found the drug to exacerbate the major seizures in some of those patients.

One unpublished survey by Geigy Pharmaceuticals (8) on over 4,000 children treated with imipramine for the control of enuresis found that five children (.11 percent) developed seizures; however, the previous convulsion history of these children is unknown. The three children reported here (who are known to have had no previous history of seizures) represent approximately three percent of those children treated with imipramine who have come to the attention of this unit. It should be noted that this unit tends to see the more seriously impaired of the children referred to this medical center. Consequently, our experience should not be construed as representative of the expected frequency of seizures among all behaviorally impaired children receiving imipramine treatment. The occurrence of convulsions in our population could possibly be accounted for by the nature of our sample, e.g., brain-injured children, who are known to be seizure-prone. Such occurrence could also be due to the higher

doses employed to treat behavior disorders, as compared with those used for enuresis. A pharmacokinetic study is currently in progress to investigate why relatively high doses of imipramine are needed for controlling hyperactive-aggressive behavior.

CONCLUSIONS

We have reported three cases of children with no prior history of seizure disorders who developed convulsions while being treated with imipramine for hyperactive-aggressive behaviors. All three had organic brain disease and did not respond to psychostimulant therapy prior to imipramine treatment. It is important to note that in two cases seizure-free response to imipramine was maintained with the addition of anticonvulsant medication. Although we cannot definitely state that imipramine provoked seizures in these three children, the findings of Fromm and associates (7) and our own observations indicate that the association is strong enough to warrant care on the part of the physician prescribing this medication. Further clinical and laboratory study into the possible association of imipramine and seizures is indicated.

Alcohol-Induced Sexual Impotence

BY FREDERICK LEMERE, M.D., AND JAMES W. SMITH, M.D.

Sexual impotence resulting from prolonged alcohol abuse may persist even after years of sobriety. The authors believe this problem is neither a psychological nor a hormonal defect but is due to the destructive effect of alcohol on the neurogenic reflex arc that serves the process of erection. The damage may be irreversible, accounting for the inability of some men to reattain potency.

AFTER TREATING over 17,000 patients for alcoholism during the past 37 years at Shadel Hospital in Seattle, Wash., we have become increasingly aware of male impotence as a serious complication of prolonged heavy drinking. At least eight percent of our male patients have complained of impotence, and in approximately 50 percent this has persisted even after years of sobriety.

Although alcohol may act as a temporary sexual stimulant, its chronic abuse can destroy sexual ability. In this regard alcohol becomes less and less effective until potency is lost, sometimes never to be regained. To quote Shakespeare: "[Drink] provokes, and unprovokes; it provokes the desire, but it takes away the performance. Therefore much drink may be said to be an equivocator with lechery." Or as one patient said: "I drank Early Times, but the result was Old Grandad."

The authors are both with Shadel Hospital for the Treatment of Alcoholism, Seattle, Wash., where Dr. Lemere is Consulting Psychiatrist and Dr. Smith is Medical Director. Dr. Lemere is also Clinical Professor of Psychiatry, University of Washington School of Medicine. His address is 308 Medical Dental Building, Seattle, Wash. 98101.

DISCUSSION

We believe that this phenomenon is caused by the stimulating and then destructive effect of alcohol on the neurologic reflex arc subserving erection. This arc theoretically includes: 1) the cerebral cortex, from which sexual thoughts arise, 2) the anterior portion of the temporal lobe, which determines intensity of libido, 3) perhaps the hypothalamus, 4) the spinal cord reflex centers for erection, and 5) the peripheral nerves that convey sensory and vasomotor impulses to and from the genital organs. The mechanism of this might be compared to the diminution of sexual ability complicating the generalized nervous system damage caused by uncontrolled diabetes.

We stress the importance of the malfunction of erection because nearly all of our patients who complained of impotence still had a strong desire for sex but, much to

their chagrin, were unable to perform. Supporting this theory that the basic handicap in alcoholic impotence is a neurogenic weakness in or absence of erection is the fact that few if any of our female patients have complained of sexual inadequacy from drinking. Women are spared the necessity of having to achieve an erection to engage in sexual relations.

It might be argued that impotence which persists after sobriety has been attained could be due to a resurgence of psychological sexual inhibitions and guilt feelings that were formerly suppressed by alcohol. That this was not the case in our patients is attested to by the fact that most of them had had a normal sex life, with or without using alcohol, until its abuse destroyed their sexual ability. In addition, their guilt was not related to sex but rather to their inability to satisfy their wives' or companions' needs in this respect. In approximately 50 percent of the cases satisfactory sexual function gradually returned after several months of abstinence from alcohol.

CONCLUSIONS

For the above reasons we do not believe that the alcohol-induced sexual impotence was psychological. Nor do we believe that it was hormonal since testosterone failed to help these patients. We do believe that it was neurogenic; that if damage to the nervous system by alcohol is severe and prolonged enough, it may be irreversible, resulting in permanent sexual impotence even during a state of sobriety. A vicious circle, or rather a downward spiral, is created by the excessive use of alcohol in which more and more alcohol is needed to effect fewer and fewer sexual results.

Unfortunately we have found no treatment for this problem except to warn heavy drinkers who are experiencing early signs of sexual failure to stop drinking in the hope that sobriety and time will restore their sexual vigor.

Symptomatology of Depressive Illness in Afghanistan

BY RAFIQ WAZIRI, M.D.

In a cross-cultural study of depressive symptoms in Afghan patients, the incidence of such "biological" symptoms as depressed mood and loss of appetite, sleep, and libido were similar to the reported incidence of these symptoms in depressed patients from a Western culture. Some symptoms that may be affected by cultural differences were also comparable, except for suicide and suicidal thoughts. The majority of Afghan patients expressed death wishes rather than suicidal intents or thoughts.

CROSS-CULTURAL STUDIES of psychiatric disorders are of interest because they shed light on which symptoms may be attributable to a basic illness and how they may be influenced by cultural variables (1). In Western cultures the symptomatology of depressive disorders has been well described from the time Kraepelin established the entity of manic-depressive psychosis. In the West endogenous depressions are characterized by dysphoric mood, vegetative disturbances (insomnia, anorexia, loss of libido and pleasure in life), self-blame and guilt feelings, motor retardation, hopelessness, suicidal thoughts, diurnal variation in mood, and other, less frequent symptoms (2–6). Pfeiffer (7), after reviewing the literature on depression based on 40 reports from 22 non-European countries, concluded that in these countries the core symptomatology of depression is quite comparable to the depressive symptoms described in the West. These symptoms include mood changes; loss of sleep, appetite, and libido; variation in diurnal rhythm; and hypochondriasis. Such symptoms as guilt, hopelessness, and suicidal tendencies are modified by cultural factors. Unfortunately, in most non-European countries facilities for the precise and detailed description of depressive syndromes have not been available, and authors have presented their findings in an impressionistic and anecdotal fashion.

This study was undertaken to describe for comparison's sake the symptomatology of depression in psychiatric patients in Afghanistan. I made the observations and gathered the data while I was a Visiting Instructor in the Department of Psychiatry and Neurology of Kabul University from January to November 1969. Since I am a native of Afghanistan and well versed in the language and culture of its patients, and have also had extensive training in the West, I was in an advantageous position to carry out this comparative study.

Dr. Waziri is Associate Professor, Department of Psychiatry, University of Iowa, Iowa City, Iowa 52240.

The author wishes to thank Dr. George Winokur, Professor and Head, Department of Psychiatry, University of Iowa, Iowa City, for his helpful comments and suggestions.

GENERAL REMARKS

The Sanayee Hospital, where this study was carried out, is the only psychiatric inpatient facility available for the 13 to 15 million Moslems of Afghanistan. The hospital is part of the University of Kabul medical complex and is under the general administration of the university, which is itself a governmental institution. The joint Department of Psychiatry and Neurology that operates this facility is staffed by one professor, one associate professor, and two assistant professors who have been trained mostly in the French tradition of psychiatry. There are 80 beds for male patients and about 16 beds for female patients. Both psychiatric and neurological patients are admitted to this facility. Sixty of the beds are occupied by psychiatric patients, about 20 of whom are chronic and have been in the hospital for more than two years. The average length of hospitalization is six to eight weeks. Although indigent patients can be admitted to this facility, most patients have to pay a nominal sum for a period of at least one month.

In an underdeveloped country the care that psychiatric patients can receive is perforce insufficient, and yet, with the extensive use of electroshock therapy and modern psychotropic drugs, the rate of admission and discharge is fairly high. Of the patients discharged, about 90 percent have improved. According to the hospital register in a period from April 1967 to January 1968, 614 male patients were admitted to the psychiatry section and 189 male patients to the neurology section. Their diagnostic breakdown is shown in table 1. Certain observations can be made with respect to this breakdown. The category of hashish intoxication is probably composed of patients with a mixed group of manic and schizophrenic reactions, with florid hallucinations and delusions that show aggressive or socially unacceptable behavior consequent to the intake of large amounts of potent hashish. Many of these patients also suffer from an acute organic psychosis. The number of manics is about 50 percent greater than the number of depressives. This may be due to the high cultural tolerance to depressed behavior in contrast to manic behavior. The diagnosis of *confusion mentale* refers to organic psychoses with an etiology other than hashish intoxication. The category of neurotic states consists of patients with hysteria, anxiety reactions, sexual impotence, and reactive or neurotic depressions.

TABLE 1
Diagnostic Breakdown of Psychiatric Patients Admitted to Sanayee Hospital, April 1967–January 1968

Diagnosis	Number	Percent
Schizophrenia	206	33.0
Hashish intoxication	127	20.5
Neurotic states	103	16.5
Mania	75	12.3
Depression	49	8.5
Confusion mentale	28	4.9
Paranoid psychosis	17	2.8
Mental retardation	6	1.0
Malingering	3	0.5
Total	614	100.0

The figures shown in table 1 in no way indicate the actual incidence of psychiatric disorders in Afghanistan. The number of patients coming to Sanayee Hospital is probably a small fraction of those who need psychiatric attention. Most of the patients either receive no treatment or are taken to the nearest holy shrine where they are kept behind doors and in chains in the belief that the evil spirits will be banished by the holy religious leader buried there. I visited one of these shrines and saw patients who were being "treated" with mild to moderate pain-producing techniques while various religious chants were recited in conjunction with exhortations for the banishment of the evil spirit. Although no fixed fee is required for a patient either to become a resident of or to receive treatment in these shrines, the relatives of the patients are expected to donate alms for the keepers of the shrines, as well as to pay for the patient's food during his stay.

METHOD

All of the male patients were interviewed by me, or by the rotating interns in my presence, or by interns alone after they had learned interviewing techniques. After concluding that the patient was suffering from a depressive illness, we gave specific attention to recording information about the set of symptoms listed in table 2. In order to be diagnosed as a depressive, the patient had to have dysphoric mood, sleep disturbances, and loss of appetite or libido. Whenever such a patient showed psychotic symptomatology but no associative thought disorders, he was diagnosed as depressive. (In going over the records of some of the patients for the previous year, I noticed that a number of patients were diagnosed as schizophrenic simply because, along with manic or depressive symptoms, they also had delusions and hallucinations.)

After the initial interviews, it was noticed that symptoms of suicidal tendencies could be subdivided into death wishes, suicidal thoughts, and suicidal intent or attempt. In Afghanistan most people speak either Pushto or Persian; neither of these languages contains easily understandable words that convey the meaning of psychic depression in a poorly educated population. Most often, in order to elicit a symptom, easily understood examples were used, and the patient was asked whether he had experienced a certain feeling or thought or had behaved in a particular manner.

The mean age of the patients in this study was 45 years, with a range of 25–70, and the mean duration of illness prior to admission was 133 days, with a range of 5–500. About 35 percent of the patients gave a history of previous depressions and 18 percent, a history of manic episodes. Most of these patients suffered from severe depres-

sions because they had often come to the hospital from faraway provinces, by poor means of transportation, and after having tried the local and immediate means of alleviation for a number of months. The impression was that they belonged to the lower and lower-middle classes in Afghanistan.

At the end of September 1969, the intake records of these patients were reviewed. Of 41 records, 37 were acceptable in that the listed symptoms recorded were either present or absent. No attempt was made to record in a graded manner the severity of these symptoms since all patients were considered to suffer from a severe depression.

RESULTS

The most common symptoms were "sadness," sleep disturbances, and loss of appetite or libido (see table 2). Most patients had depressed facies; only three appeared to have a "smiling depression." Generally, patients had no words to describe their feelings of sadness. They were able to differentiate these feelings from the feeling of grief like that occasioned by the death of a dear one. Many described their feeling "as if a strong hard hand was squeezing" their "hearts." Thus, this feeling of sadness had a special quality. This was the most stressed symptom from which the patient wanted relief.

The complaint of sleep disturbances was elicited from 92 percent of the patients. Most complaints were expressed in terms of "I can't sleep," and only after further inquiry did it become apparent that most of the patients suffered from middle to terminal insomnia. Vegetative disturbances were also quite common, with loss of appetite being more frequent than loss of libido. Most patients expressed a loss of a sense of pleasure (e.g., one patient said that he no longer enjoyed his small children, who used to be a great source of pleasure to him). Loss of appetite and libido were quite common. More than 50 percent of the patients with these symptoms also reported a loss of weight. Two delusional patients would not eat, fearing that their food might have been poisoned. Crying spells were the next most frequent symptom that was bothersome to the patients. Most of them did not recall having cried since their childhood, and most often they could not give a reason why they would suddenly burst into tears. They would do their best to be alone so that nobody saw their tears. Obsessive thoughts were generally related to financial and business problems and rarely to guilt feelings or religion. Psychomotor retardation was observed more often in the older age group and especially in patients who had been sick for longer than three months.

In response to a question about how the patient viewed life, 54 percent answered that they "wished they were dead" or that they had "prayed to God to take their life away." When they were asked whether they had any thoughts of killing themselves or had attempted or intended to kill themselves, 20 percent admitted to passing thoughts of suicide but had banished these by thinking of the great sin they would be committing. Only six of the 37 patients (14 percent) admitted having had suicidal intentions, and only one (2.7 percent) had actually attempted suicide by cutting his throat. This latter patient was referred from surgery after his wound had been treated for about ten days.

Hallucinations and delusions were not too common. Most hallucinations consisted of the patient's hearing voices that accused him of sinful acts or of seeing the Jinns, which, according to these Moslem patients' beliefs, are ubiquitous creatures of God. Delusions were also culture-bound; for example, one patient, who had recently been married, became depressed soon after and lost his libido; he thought that another man who wanted his wife had put a charm on him. Sometimes patients would also have nihilistic delusions, such as a belief in the loss of their stomachs or testicles. The frequency of symptoms in different age groups appeared to be uniform, but since

TABLE 2

Occurrence of Symptoms in Different Age Groups and Comparison of Occurrence in Two Studies

Symptom	Age Range			Percentage of Patients Showing Symptoms

there were so few patients in some age groups, valid comparisons could not be made.

DISCUSSION

Given stringent diagnostic criteria for depression in one culture, it is possible to describe and compare the symtomatology of depression in another. The findings of this study show that the core symptoms of depression are quite consistent cross-culturally. This stands to reason in view of the large amount of evidence (8–13) indicating that endogenous depression is a genetic illness and therefore biologically determined. The most common symptoms of depression in patients from Western culture and in patients from Afghan-Moslem culture are intense dysphoria, sleep disturbances, and loss of appetite and libido. Whereas these core symptoms have been observed to occur with high frequency in different countries of different cultural backgrounds (7), certain other symptoms of depression, such as crying spells, guilt feelings, suicidal thoughts and acts, and obsessive thoughts, may have cultural determinants. In a careful study of depressions in American men of comparable mean age (45.9 years) Baker and associates (14) reported the frequency of these symptoms as follows: dysphoria ("sadness"), 100 percent; sleep disturbances, 68–84 percent; and loss of appetite, 87 percent. These figures correlate fairly well with the incidence of these symptoms in Afghan patients (see table 2). The frequency of two other "biological" symptoms—variations of diurnal rhythm and psychomotor retardation—in American patients was 48 percent and 65–71 percent, respectively, and therefore are not too well correlated. In Afghan patients the incidence of hallucinations was 33 percent, while in the American patients only nine percent reported this symptom. However, in an earlier study Rennie (15) reported that 25 percent of patients with severe depressions had hallucinations. The high incidence of hallucinations in the Afghan patients may have been due to the long duration of the disease, leading to physical debilitation. The frequency of delusions in the two studies appeared to be comparable (16 percent as opposed to 19 percent).

Of the symptoms that presumably are not biologically determined, the incidence of crying spells in the two studies was quite dissimilar (78 percent as opposed to 61 percent). The higher frequency of crying spells in the male patients in my study was somewhat surprising, because in Afghan culture crying is shameful for a man but condoned in a woman. Whenever a boy cries because of a hurt he has received, he is admonished to stop since "only girls cry." This cultural sanction against crying is not unlike that seen in American culture.

Of the other two categories of symptoms—guilt feelings and suicidal thought and tendencies—the incidence of guilt feelings in this study was similar to that in the American report (39 percent versus 32 percent, respectively). In this regard Murphy and associates (1) proposed that the higher incidence of guilt feelings in Western cultures was due to religious differences. Since Islam, like Judaism and Christianity but unlike Buddhism, Hinduism, and the African religions, seems to stress the idea of sin, the differences that Murphy and associates pointed out are probably not applicable in this case. Fakhrel-Islam (16), in a study of depressed Christian and Moslem patients in Cairo, found that the frequency of guilt feelings in the two groups was similar. In both groups those with a higher education seemed to have more guilt feelings than illiterate patients. In my study, class as well as education also appeared to be important in the incidence of guilt feelings in the patient; those from a higher social class showed more guilt feelings.

Suicidal thoughts, attempts, or intentions were much less frequent in Afghan patients than in patients in the West. Gobar (17) reported one of the lowest suicide rates in the Afghan population (0.25/100,000). Since a large number of Afghans who are depressed never reach medical facilities and are never followed up, Gobar was not able to ascertain the incidence of suicide in the depressed. With the meager data available, it may be safe to assume that the frequency of suicide is low in the depressed patients of Afghanistan. It is generally true that suicide rarely occurs without suicidal thoughts; hence it would seem that the frequency of suicidal thoughts would provide some information on the risk of suicide in these depressed patients. Although death wishes were fairly common in the Afghan patients, only 20 percent had suicidal thoughts, as compared with 55 percent of the American patients studied by Baker and associates (14). Eleven percent of the Afghan patients had expressed suicidal intentions and could probably be included in the group of patients with suicidal thoughts, bringing the total in that group to 31 percent. In only one patient was a suicidal attempt the reason for admission, while Winokur and associates (6) found that 13 percent in their study had been admitted for a suicidal attempt. One other symptom for which the patients in the two studies were dissimilar was obsessive thoughts. This symptom occurred with much greater frequency in the depressive Afghan patients (58 percent) than in the American patients (six percent). No data were available on whether these obsessive thoughts developed de novo during the depression or existed in the premorbid period.

A question that may arise is whether it is valid to compare two studies that may be disparate in the type of patients as well as in the data-gathering techniques. There is no doubt that better and more tightly comparable studies could be carried out in order to delineate similarities and dissimilarities in the clinical aspects of depressive illness in different cultures. In this study, although not satisfying all the criteria for a good cross-cultural comparison, I have attempted to show that the incidence of certain biological, as well as psychological, symptoms of depression in Afghan patients is comparable to the same symptoms in patients from a Western culture.

Quaalude Alley: A One-Way Street

BY T. PETER BRIDGE, M.D., AND EVERETT H. ELLINWOOD, JR., M.D.

Methaqualone (Quaalude), a nonbarbiturate sedative, was introduced to the American public as a nonaddicting drug with low abuse potential. Unfortunately, it has become the newest drug of abuse. The authors outline the effects of the drug and discuss two patients who had adverse effects after abusing Quaalude. They stress the need for tighter controls on nonbarbiturate sedatives.

During both conventions (Republican and Democratic), Flamingo Park was known as "Quaalude Alley" in deference to the brand of downers favored by most demonstrators. Quaalude is a mild sleeping pill, but—consumed in large quantities, along with wine, grass and adrenalin—it produces the same kind of stupid, mean-drunk effect as Seconal (Reds). The Quaalude effect was so obvious in Flamingo Park that the "Last Patrol" caravan of Vietnam Vets . . . refused to even set up camp with the other demonstrators . . . . The last thing they needed was a public alliance with a mob of stoned street crazies and screaming teenyboppers.

—H.S. THOMPSON (1, p. 44)

WITHIN THE LAST SIX MONTHS "Quaalude Alley" has come to the Durham, N.C., area. Methaqualone (Quaalude, Sopor, Somnafac, Parest) is repeating a pattern familiar to those acquainted with the history of nonbarbiturate sedatives. Reports from all over the United States are quickly labeling methaqualone the newest drug of abuse (1–3).

For those who have watched the development of nonbarbiturate sedatives or who have watched the history of methaqualone in other countries the story is not surprising—only disappointing. It is disappointing that once again a drug classified as a nonbarbiturate sedative has been introduced on the American market as nonaddicting and with low abuse potential (4) only to be proven otherwise. Essig, in 1964, reported the history of such sedatives as glutethemide (Doriden) or methyprylon (Noludar), which were hailed as nonaddicting when they first entered the marketplace (5). This claim proved not to be valid.

HISTORY OF METHAQUALONE

The initial history of methaqualone is similar to the history of these drugs. Gujral introduced the drug in the 1950s in India. It has the following properties: 1) hypnotic effects comparable to those of barbiturates, 2) anticonvulsant effects against experimentally induced seizures, 3) antitussive effects comparable to those of co-

The authors are with the Department of Psychiatry, Duke University Medical Center, Durham, N.C. 27710, where Dr. Bridge is a resident and Dr. Ellinwood is Associate Professor of Psychiatry.

deine, and 4) weak antihistaminic effects (6). The drug has no analgesic effects but does enhance the analgesia produced by codeine (6). Although initially thought to be relatively free of side effects, current reports indicate that hangover, dizziness, urticaria, and paresthesias can occur when the drug is used (6). Kessell also reported that epistaxis, menstrual disturbance, tongue changes, dryness of the mouth, depersonalization, and cracking at the angles of the mouth have occurred (7).

Although the manufacturers claim that methaqualone (in contrast to the barbiturates) does not suppress the dream stage of sleep, or rapid eye movement (REM) sleep, Kales and associates have brought this claim under question. This group showed not only that methaqualone (300 mg.) produced REM suppression, but also that REM rebound occurred upon withdrawal of the drug (8). This group had previously shown this suppression and rebound to be characteristic of drugs of dependence (8, p. 223). The *Medical Letter on Drugs and Therapeutics* stated that no clinical consequences of the suppression of REM sleep by sedatives have been shown and that drugs such as methaqualone should continue to be judged by the traditional properties: "rapidity of sleep induction, total duration of sleep, hangover effects, addiction and abuse properties, and toxic properties" (9). Notably lacking among these studies have been any published results of animal toxicity research. We were unable to locate any such studies, and inquiries at the manufacturers only produced the reply that "in-house" studies have been made that did not show abstinence syndrome. These reports were not published (10).

At approximately the same time that methaqualone was introduced in this country, several articles appeared in the British literature reporting addiction to and withdrawal symptoms from methaqualone. In 1966, Madden reported four cases that met three of the four criteria of the World Health Organization for drug dependency of the barbiturate type (11). It was unknown in these four cases whether or not the patients showed abstinence syndrome upon withdrawal of the medication. In 1967, Ewart and Priest reported the case of a 47-year-old man who showed withdrawal symptoms after the abrupt cessation of excessive amounts of methaqualone (60 150-mg. tablets per day) (12). In 1969, DeAlarcon reported an increase in the abuse of methaqualone, especially among former heroin addicts who reported enjoyment of the "buzz" they received from the drug (13).

Two patients who were recently seen at the Duke Medical Center emergency room seem to follow the pattern suggested by these earlier British articles.

CASE REPORTS

Case 1. A., a 41-year-old unemployed man, appeared at the emergency room in an anxious, agitated state. He admitted to alcohol abuse of two weeks' duration (a fifth of wine per day), which was confirmed by his family. A mental status examination revealed that he had difficulty with recent memory; he was oriented as to person, place, situation, and space but not to time. No hallucinations or paranoid ideation were present. With his family's cooperation, he was detoxified on an outpatient basis using chlordiazepoxide. Upon follow-up examination, the mental status abnormalities noted had cleared. During this exam, it was learned that the patient had been abusing Quaalude (up to ten tablets a day) for approximately three months and had discontinued this approximately one week prior to his initial contact with the emergency room. He stated that the cause of his drinking binge was related to his failure to maintain adequate supplies of Quaalude.

Case 2. B., a 37-year-old female musician, appeared in the emergency room in a semi-stuporous state after a motel operator found her talking "crazy talk" on the phone. A small shopping bag full of medications brought with her contained pentazocine (Talwin) and Quaalude (the only centrally active drugs present in the collection). Blood assay revealed detectable nontoxic levels of barbiturates. A long history of drug abuse was confirmed by the patient's family. Hospitalization was declined by both the family and the patient on the basis that previous psychiatric hospitalizations at a university center "hadn't done any good." The patient had been diagnosed as a borderline personality during this hospitalization. The patient was observed overnight in the emergency room and released the next day in a stable condition. She stated that she used Quaalude and barbiturates interchangeably and often simultaneously to escape discomfort in her life.

DISCUSSION

Among a group of casual drug users, both men and women, known to the clinic staff at this hospital, a brief survey was conducted concerning methaqualone. This population consisted primarily of college-age students. Of a total of 26, 17 responded that they had used the drug, and it was exclusively known to them as Quaalude. All had been introduced to the drug by friends within the past six months. The number of uses varied from one to ten. The sources for this medication were listed as friends (i.e., street purchase), family doctor, and student health service. All of the subjects described the sensations produced by the drug as pleasant, with one exception. This latter subject listed nausea and a feeling of generalized discomfort. The others listed such feelings as "buzz," "rush," "really drunk," "peaceful," "calm," "staggering," and "happy." One of them replied: "It's a great low calorie drink—you don't have to pump yourself full of booze." The majority of those familiar with the drug believed it to be easily available but not widely known to the student population *yet* (their emphasis). By admission, drug use among this population included marijuana, amphetamines, barbiturates, and lysergic acid diethylamide.

The previously mentioned reports concerning the experience in Durham and apparently throughout the United States currently indicate that methaqualone has become another drug of abuse. Despite supposedly tight Food and Drug Administration controls, methaqualone was introduced as a nonaddicting drug after reports had appeared warning of both the abuse potential of any drug of the nonbarbiturate-sedative classification (6) and of the abuse potential of methaqualone in particular (14). It is our belief that by now sedatives should be considered

"guilty" of addiction potential until proven otherwise, and that this proof—1) development of tolerance, 2) abstinence syndrome upon withdrawal of the drug, and 3) continued use by animals that are tolerant to the drug when self-administration devices are made available—should be made in the laboratory, not on the street.

Quaalude Alley is a one-way street to tighter controls such as the English have imposed (15). Once again they have preceded us with methaqualone, both in use, in abuse, and, one hopes, in control.

Participatory Management in Psychiatry

BY DAVID E. RASKIN, M.D.

In psychiatry, the concept of participatory management has been developed in the therapeutic community and elsewhere. The industrial management literature reveals that, although scientific management and human relations theorists saw no necessary conflict between management and worker, more recent writers have noted great conflict between organizational and individual needs. The author attempts to translate the industrial experience to psychiatric bureaucracies and highlights the basic conflicts between participatory management and authority, responsibility, and conflicting value systems.

PARTICIPATORY MANAGEMENT is a principle of therapeutic communities, psychiatric hospitals, and community mental health centers. In education, educators and students are engaged in the planning of both secondary school and university programs. Community action groups are demanding greater participation in education and in health. In psychiatry the question of resident participation in program planning and evaluation is very much with us. This paper will consider certain problems inherent in participatory management and will particularly focus on data from the business community and the psychiatric ward.

Dr. Raskin is Residency Coordinator, Department of Psychiatry, University of Chicago, 950 E. 59th St., Chicago, Ill. 60637.

The therapeutic community concept developed out of the World War II experience of psychiatrists' needing to find rapid and effective ways of handling large numbers of patients. The moral treatment (1) of the nineteenth century was certainly an early form of the therapeutic community. Such communities vary in terms of value systems and specific approaches. I will focus on the ideas of Maxwell Jones (2–5) in this paper since he is one of the major proponents of the therapeutic community, particularly with regard to participatory democracy.

Jones (2) listed the following goals for a therapeutic community: 1) active rehabilitation as opposed to custodialism and segregation; 2) democratization in contrast to old hierarchies and formalities of status differentiation; 3) permissiveness in contrast to stereotyped communication and behavior; and 4) communalism as opposed to specialized staff roles limited to the doctor.

Jones has written extensively about leadership and decision making by consensus. "In a therapeutic community communications at all levels are made as efficient as possible, and decision-making by consensus is aimed at. Unilateral decision in any important matter affecting other people is avoided" (5, p. 24). So ideally, the therapeutic community, as conceived by Jones, involves an attempt to maximize the democratization of communication, leadership, and decision making in the interest of psychological growth of patients and of staff.

APPROACHES

The search for effectiveness and efficiency in organizations gave rise to the classical theory of administration (6). This "scientific management" approach saw workers as motivated by economic rewards and the organization as characterized by a clear division of labor, specialized personnel, and a hierarchy of authority. Arising as a reaction to the scientific management approach was the human relations school (6). Human relations emphasized the emotional, unplanned, nonrational elements in organizational behavior. It also pointed out the need for communication and for the participation of workers, and the importance of leadership. The classical approach recognized no conflict between man and organization. It assumed that what is good for management was good for the worker, that higher efficiency leads to higher profits, which lead to higher wages and greater worker satisfaction. The human relations approach, on the other hand, pointed out that workers have many other needs and that if management paid attention to the cultural and social needs of the workers, this would lead to increased worker satisfaction and productivity.

Both the scientific management and human relations approaches saw no necessary contradiction between the needs of the worker and the needs of the organization, although each school placed a different emphasis on what should be done to maximize organizational needs and worker satisfaction.

The structuralist approach (6) is a synthesis of the classical school and the human relations school, drawing on the work of Weber and Marx as well. The structuralists recognize inevitable strains between organizational needs and personal needs, between rationality and nonrationality, and between formal and informal relations. The structuralists in addition studied hospitals, prisons, churches, armies, etc., as well as business and industrial organizations.

The human relations school has indicated some ways in which frustrations may be reduced, but structuralists insist that there are limits to the degree to which this can be achieved: A sense of community, primary relations, and communication blocks are important but are not complete substitutes for material rewards. Management has been criticized for attempting to provide inexpensive symbols of prestige and affection instead of an increase in wages. What can be created is a false sense of participation in decision making when, in fact, a decision has already been made and the real purpose of a conference is to get those who are lower in rank to accept that decision.

So in addition to the concern about the inappropriate use of human relations concepts, the structuralists feel that the human relations group focuses on a narrow range of variables (i.e., informal relations) without considering their relationship to formal organizational structure; overemphasizes the importance of informal work groups; underemphasizes the relationship between organization and environment; and overemphasizes social rewards and underemphasizes material rewards. For example, in a recent article Henshel (7) stated that "... those who are determined to automate and institutionalize the corporate presidency often overlook the fact that no committee or formula is able to make the kind of subjective evaluation that a president must make when he decides on a major course of action.... There can be endless debate on how a thing is to be done; but there can be no final sharing of the decision on what is to be done." This is up to the president.

Maslow stated:

> The relationship of the boss to the people whom he might have to fire or punish is, if we are realistic about it, not a friendly relationship among equals. Our attitude toward anyone who has power over us, even if it is the most benevolent power is different from our attitude toward those who are equals.... The facts do seem to support participatory management in so far as the culture is good enough, the people involved are psychologically healthy, and the general conditions are good (8).

Gomberg wrote:

> Democratic management of industry has become a modish philosophy shared by avant-garde students of the American industrial enterprise.... Benevolent autocrats operating within a competitive institutional framework seem to provide the most effective combination of economic achievement and political restraints. Industry's democrats have confused a benevolent paternal style of velvet-gloved autocracy with democracy (9).

CONFLICTS

It is evident that feelings are still strong about the issue of participatory management. Some still see it as a panacea; others, as a hoax; and many as a partially attainable goal but not without a great deal of conflict. A recent experimental study (10) concluded that a strong positive association between group collaboration and organizational performance remains to be demonstrated.

In psychiatry the current wave of participatory management, role blurring, decision making by consensus, and multiple leadership represents a human relations approach. Maxwell Jones, a human relations theorist in terms of psychiatric organizations, nevertheless recognizes the pitfalls and writes about them. He states, for example:

> In theory one tends to postpone action until such times as consensus has been achieved. Sometimes this is quite impractical, particularly in crisis situations, when sanctions appear to be called for—at least in the opinions of some members. The important thing is that a delay should not be at the cost of the over-all feeling of security within the hospital community. Any society needs to feel that there are ultimate sanctions that will be invoked—irrevocably if required. Without such a belief, backed up by actual demonstration, society, or at least some of its insecure members would anticipate anarchy (5, p. 65).

Jones goes on to say: "No matter how democratic and equalitarian the social structure of a therapeutic community may be, there is never any doubt that the ultimate authority rests with the psychiatrist. Whether he uses this authority in making unilateral decisions will depend a great deal on the circumstances" (5, p. 66).

> [The] question of elaborating the role of a patient to one of therapist is, I think, one of the fundamental tenets of therapeutic community procedure. This concept is often mistakenly seen as handing over ultimate responsibility to the patients. This, in my opinion, is not practicable and what one wishes is to give the patients optimal responsibility compatible with their overall capacity at any one time, and in no sense does the staff or the doctor in charge relinquish his ultimate authority which merely remains latent to be invoked when necessary (4, pp. 691–692).

Although Jones would like to promote the ideas of participatory management and patient participatory responsibility, he nevertheless inserts qualifications in his writings. In the "crunch," participatory management needs to be discarded, and the doctor who is ultimately responsible decides. There is not enough talk in community mental health centers, psychiatric hospitals and wards, and departments of psychiatry about these unavoidable conflicts in the free use of participatory management.

Inevitable conflicts must exist in psychiatric organizations; participatory management is not a panacea. There are always issues of authority, responsibility, and conflicting value judgments. Charismatic leadership can create the impression that there is really a participatory democracy. Often, this represents the followers' need to please the leader and to adhere to his values and philosophy. Decision making by committee is useful, but some issues are not the kind that can await committee decision or patient staff decision, and in such cases the leader steps in. Participatory democracy in psychiatry should not hide the fact that such people as nursing assistants are horribly underpaid, poorly trained, and without viable career ladders. These issues affect morale and efficiency and are not going to be solved by participatory management.

The self-actualization theory is one aspect of motivation for some human beings but is not translatable to *the* motivating force in a psychiatric hospital or community mental health center. Some people want to be told what to do; some patients and staff members are unable to accept the role of management equal.

The structuralist concept of inevitable conflict within an organization is most relevant to psychiatric systems. Problems of the articulation of formal and informal structure, of material versus social rewards, of the use of human relations approaches to placate nursing assistants, and of differences in salary, education, power, and responsibility cannot be hidden or solved by patient-staff meetings or by ward sensitivity groups.

But the outlook is not bleak. There is a conflict between participatory management and institutional efficiency. Nevertheless, communication systems can be vastly improved, even if decision making is not always shared. Some areas are fruitful for participatory management; others are not. These should be spelled out. What we need to avoid is the promise of participatory democracy without being able to deliver it. If we recognize the conflicts, are honest about them, and attempt to deal with them in hospitals, mental health centers, and departments of psychiatry, all those involved may benefit.

Sandor Rado
1890–1972

Dr. Sandor Rado, pioneer psychoanalyst and psychiatric educator, died in New York City on May 14, 1972, at the age of 82.

Dr. Rado received his first university degree, Doctor of Political Science, in Hungary at the University of Budapest at the age of 21. However, late in 1910 he read a pamphlet about Freud and psychoanalysis by Sandor Ferenczi. This new concept, together with his dissatisfaction with the social sciences, led him to enter medical school. He joined Ferenczi's study group, which was soon organized as an official psychoanalytic society, and he was active in psychoanalysis for the rest of his life.

Dr. Rado graduated in medicine in 1915 and was certified as a specialist in psychiatry in 1923, at which time he was invited to become a member of the faculty of the newly formed Psychoanalytic Institute in Berlin, where he remained until 1931.

In 1931 Dr. Rado was invited to New York City as the first educational director of the newly formed New York Psychoanalytic Institute. He remained in this post until ideological differences with some of the tradition-minded members of the education committee led to his departure in 1941. Almost immediately he began planning a new psychoanalytic training center. In 1944 he was appointed clinical professor of psychiatry and director of a newly established psychoanalytic clinic for training and research in the Department of Psychiatry of the College of Physicians and Surgeons of Columbia University, where he served until his retirement in 1955. With the creation of this institution as part of the medical school in a major university and its associated clinical facilities, Dr. Rado approached an ideal for psychoanalytic education and service that he had gradually evolved: that psychoanalysis must be a part of the medical curriculum; it must fulfill the criteria of biologic science in its theoretic methodology and, most importantly, have access to the fullest clinical facilities and maintain close cooperative liaison with all other behavioral or biologic sciences.

He foresaw that the future of psychoanalysis and psychoanalytic education depended on a transition from its origins in theoretic and clinical insularity to administrative integration and cooperative daily function with the body of medical, educational, scientific, and clinical institutions. Scientific discipline and scientific cooperation were necessary ingredients of psychoanalysis.

Dr. Rado ignored retirement and in 1956 founded his fourth center of graduate training in psychoanalysis as the New York School for Psychiatry, from which he retired as dean emeritus in 1967.

Dr. Rado revised a number of the original theories of Freudian psychodynamics on the basis of careful clinical research, but while a brilliant theoretician he was known best as an exciting and stimulating teacher, the most stimulating I have ever known.

Henry Adams said, while Dr. Rado was still in college, "A great teacher affects eternity—he can never tell where his influence stops."

JOHN M. COTTON, M.D.

LETTERS TO THE EDITOR

The Responsibilities of Psychiatry to Medicine: A Debate

Editor's Note: An unusually large number of letters has been received in regard to Dr. George Engel's editorial "Is Psychiatry Failing in Its Responsibilities to Medicine?" (June 1972 issue). To save space and to avoid repetition we have abstracted the letters below.

SIR: In his editorial Dr. George Engel called attention to a problem that has been troubling many psychiatrists. He questions the right of those who decided to eliminate the requirement of an internship for psychiatric training programs and calls upon those who share his concern to let their voices be heard.

I was a member of the Residency Review Committee at the time it recommended elimination of the internship requirement. I felt that many questions had not been adequately considered. For example, should psychiatric residents be proficient in physical examinations and in detecting or recognizing organic disease, and should they have some competence in treating organic disease? Should they have this proficiency before they start, during, or on completion of their psychiatric training? If such proficiency were present on starting psychiatric training, what test would be used to ascertain or measure it? Could graduation from medical school or medical licensure be used as the criterion? To what extent is there variation from one school to another? How much knowledge of the basic medical sciences and of other clinical specialties should be expected of a beginning trainee? What are the essentials of an internship that are supposed to be covered by training programs which accept trainees without internships?

Traditionally, psychiatrists have pointed to their medical backgrounds and competence as the major features that distinguished them from psychologists, social workers, and other emerging allied mental health professionals with whom they are increasingly equated by the public and by psychiatrists themselves. Psychiatrists can rely on this distinction only to the extent that they continue to see themselves as physicians rather than as just psychotherapists. The question repeatedly arises whether it is necessary or wise for the psychiatrist to spend all the time he does in his medical training, his internship, and his residency if he is going to end up doing essentially what others with much less training are said to do equally well.

The roles of the psychiatrist and allied mental health professionals have become so blurred that there is some uncertainty about psychiatry's viability as a medical specialty. It is of interest that *Time* magazine no longer includes psychiatric news items under the section "Medicine." They are now in a new section called "Behavior." Dr. Engel's question, "Is Psychiatry Failing in Its Responsibilities to Medicine?" might well be rephrased, "Does psychiatry regard itself as a medical specialty or as something else that is health-related but not medical?"

NORMAN Q. BRILL, M.D.
Los Angeles, Calif.

SIR: Dr. Engel's comments concerning psychiatry's movement away from medicine are timely and sadly accurate. I, too, feel disturbed by what seems to be a growing tendency within our profession to look upon anything that smacks of medicine or of the "medical model" as bad and upon anything with "human services" in its title as good. I question the wisdom of a federal effort to support health care that provides millions of dollars for sometimes ill-defined services, while funds for training and crucial research are being cut to the bone. Further, I am dismayed when I hear medical colleagues in other fields complain, "You psychiatrists are no longer interested in working with sick people, but who do we get to help us with our patients?"

Because I share Dr. Engel's concerns, I feel it is most unfortunate that he has causally linked the issue of the extinction of the internship with the need for a holistic approach to patient care. The abandonment of the internship requirement was an action taken in response to the severe shortage of health manpower in our country and with the expectation that the long-overdue revision of medical curriculum would occur. Many hoped that this decision would allow all of medical education to be seen as a continuum and that the artificial boundary between medical student and novice physician would be largely eliminated.

Few can challenge the necessity of a physician's receiving broad clinical training and of his having experienced primary responsibility for a variety of patients before embarking on a course of specialty training. Breadth of diagnostic vision, a holistic approach to patient care, maturity of judgment, and self-confidence, tempered by the appropriate acceptance of one's limitations, are direct benefits. This experience should never be eliminated from a young physician's education.

But to imply that the internship is the only opportunity for such responsibility is an argument predicated more upon structure than upon substance. The issue is, rather, why has it been so difficult for curriculum committees of medical schools to provide the generic medical student with a variety of primary clinical responsibilities. Is it perhaps because patient-hungry specialist residents are leaving an insufficient amount of clinical material for students? Or is it because too many distinguished educators have been digging their heels in against any change in curriculum rather than working toward the development of a more realistically *integrated system* of medical education?

JAMES S. EATON, JR., M.D.
Washington, D. C.

SIR: Dr. Engel's editorial is appropriate and timely. The ruling that one can go from medical school into a psychiatric residency has been bothering me for some time. One of my fears was recently realized in working as a psychotherapy supervisor with a second-year psychiatric resident who entered his residency directly from medical school. He was quite inadequate when, like all other psychiatric residents, he was required to carry out the duties of a licensed medical doctor. Having had practically no clinical experience, he daily found himself in spots in which he did not know how to respond effectively. Because of this, he was unable to perceive the reality of the therapeutic situation.

This young man grasped at every new idea placed before him by the school of psychiatry, gave himself no time to test any of

these, and ended up feeling inept, but defensive. I believe he will continue to have great difficulty working with people in a therapeutic manner. I feel sorry for him and for psychiatry. I presume that this mistake will be repeated many times and that psychiatry will lose in the long run.

As a viable part of medicine, psychiatry should utilize and be utilized by all of medicine. Without experience in general practical medicine the psychiatrist cannot be the doctor who can treat the whole person. I feel that psychiatry should continue to require at least a year's rotating internship before the psychiatric residency.

KENNETH E. GODFREY, M.D.
Topeka, Kans.

SIR: Dr. Engel's editorial is indeed very provocative. It appears to me that Dr. Engel has already concluded that the psychiatrist of tomorrow who received Board certification without the requirement of an internship is a liability instead of an asset to APA. This is like a verdict without a trial.

Nowadays, unless one is going into general or family practice, a straight internship is the choice for the specialty minded. It would be beneficial for an aspiring psychiatrist to be exposed to the various medical specialties before completely devoting himself to his discipline, but would a straight psychiatric internship do it? What, then, does an ambitious physician lose by going directly into a psychiatric residency?

If the physician is fully aware of his responsibilities as an M.D., he should "approach the problem of the patient before him in a holistic manner, regardless of his special discipline." Medical educators should see to this before giving him his M.D. degree.

ARISTIDES E. PENETRANTE, M.D.
Buffalo, N.Y.

SIR: The vexing nature of the relationship between psychiatry and the rest of medicine seems to have left the arena of intellectual challenge and investigation and entered a political field guided by intuition and faulty reasoning. Dr. Engel's editorial aptly points out the hazards of the current approach. He raises a number of questions about how such a major decision as the abandonment of the internship requirement could be made in the absence of complete discussion and debate. Further questions could also be raised. What evidence was cited in making such a decision? What experiments were performed? What evaluations of psychiatrists' skills took place?

The advocates of eliminating the internship requirement have probably correctly diagnosed what is wrong with psychiatry but have prescribed the wrong treatment. By examining what many psychiatrists do in their day-to-day work it became obvious that much of it had nothing to do with medicine and that traditional medical education was inappropriate for these people. Thus, by changing the education a psychiatrist would receive it would be possible to make his training conform to what he does. But such an approach misses the point (as Engel indicates) that what is wrong with psychiatry may well be that psychiatrists often do not practice medicine. The cure for this is to encourage psychiatry to continue to identify with medicine.

A closer look at the people who fail to see the hazards of our current direction might well reveal a large number of psychiatrists who entered the profession as an escape from the responsibilities of medicine without a loss of prestige or financial recompense. Many trained during an era when intensive psychotherapy was exalted and psychiatric residents rarely entered the medical or surgical wards of their hospitals. Some of them have risen to positions of sufficient power to influence the future direction of our profession but are doing so from a base of narrow, nonmedical personal experience.

Ironic as it may be, just as psychiatry appears to be entering adulthood and the need for our talents as physicians is the greatest it has ever been, we are threatened with a retreat, or at least a failure to continue to grow.

ARNOLD WERNER, M.D.
East Lansing, Mich.

SIR: As a young psychiatrist, I was moved by Dr. Engel's editorial. Dr. Engel senses something wrong with contemporary psychiatry, and in this he is quite right. However, he chooses to view the abandonment of the internship as the "single" important factor in the separation of medicine and psychiatry.

I do not believe that Dr. Engel realizes that today's established psychiatrists are the physicians who elected to adopt a mind-body dualism in psychiatry and who abandoned treating the whole person in favor of abstract, intellectual ideas on mental processes. Today many well-established psychiatrists are the greatest abusers of psychotropic agents, being unaware of their pharmacology, toxicology, and interactions with other drugs.

One hopes that it will be the young psychiatrists who can properly use psychotropic medications, counteract drug side effects, treat intoxications, and relate organic disease to altered emotional states. We must also be trained as specialists in many forms of psychotherapy by means other than the basic psychoanalytic concepts that have so separated psychiatry from general medicine and surgery.

I suggest that concerned men like Dr. Engel devote their energies to producing basic, well-rounded, commonsense psychiatric residency programs where the important types of psychotherapy and psychopharmacology and their relationship to general medicine can be taught in a comprehensive and practical manner.

I believe that the correlation of these concepts with clinical work in areas where medical specialists are urgently seeking assistance from psychiatrists is more valuable than a year of starting I.V.s, drawing blood gases, and changing bandages.

However, I do appreciate Dr. Engel's keeping this important subject alive; it is only through the interchange of ideas that we can improve the standards of psychiatry and maintain it as an essential, integral part of medicine.

ROBERT T. LONDON, M.D.
New York, N.Y.

SIR: I am writing to express my support for the position taken by Dr. Engel in his recent editorial that deplores the dropping of the internship requirement. I share his views, as well as those of Dr. John Romano ("The Elimination of the Internship—An Act of Regression," May 1970 issue) on the same subject. I am hopeful that the decision will be reversed.

JAMES C. BECK, M.D., PH.D.
Cambridge, Mass.

SIR: As a former student of Dr. Engel's and as one who has carefully weighed his advice, as well as that of Dr. John Romano ("The Elimination of the Internship—An Act of Regression," May 1970 issue), before deciding to enter a psychiatric

residency without an internship, I feel obligated to answer Dr. Engel's questions about psychiatry's responsibilities to medicine. I share many of Dr. Engel's concerns about the importance of teaching the psychosocial approach in medicine to counteract medicine's growing impersonality and of studying psychosocial problems and the role of psychosocial factors in disease. However, to blame any real or imagined failings in these areas on the elimination of the internship is obviously illogical, since this change is so recent that the number of psychiatrists who have finished training without an internship is minuscule. The point, as I see it, is that medical internships are no longer devoted to the care of the sick, but rather to learning about diseases. Perhaps one place to stress the importance of psychosocial forces would be to humanize the internship experience.

Dr. Paul Griner and I expressed concern that clinical skills in evaluating and treating patients have been hampered by reliance on laboratory tests at the expense of clinical data (1). Medical schools provide plentiful opportunities for students to become actively involved in caring for sick patients. Unlike Dr. Engel, I see no contradiction in physicians who are primarily interested in the psychosocial aspects of medicine proceeding directly to that.

Dr. Engel avoids the fact that all of the areas which he is concerned about and to which he has devoted his professional life are only part of psychiatry. Psychiatry's primary obligation is to deal with the emotional well-being of individuals and groups and, as such, we are as much a part of the mental health disciplines as of medicine.

Finally, I would suggest that rather than engaging in futile calls to action in order to hold back the winds of change, Dr. Engel now has an opportunity to test some of his hypotheses by randomly accepting some residents at the University of Rochester who have not had an internship and seeing if, indeed, there are measurable differences during residency, as well as during later life.

REFERENCE

1. Griner PF, Liptzin B: Use of the laboratory in a teaching hospital. Ann Intern Med 75:157–163, 1971

BENJAMIN LIPTZIN, M.D.
Charlottesville, Va.

SIR: I was most encouraged by Dr. Engel's brief, but excellent, editorial. I think psychiatry has failed medicine in several ways.

It was a bad mistake to drop the internship requirement for residency training in psychiatry. This is where the new physician discovers what it means to be responsible for the lives and health of others.

Our greatest failure to medicine is the apparent failure of many to realize that the concepts guiding the psychiatrist should be the same as those guiding other physicians. This failure has taken the specialty far afield from medicine.

HAROLD M. VOTH, M.D.
Topeka, Kans.

SIR: Dr. Engel's opinion regarding psychiatric training deserves the urgent attention of all psychiatrists. It should create a thrust to bring psychiatry back to where it belongs—to medicine.

If psychiatry is to remain a "branch of medicine," we psychiatrists must retain our birthright as physicians. A general internship uniquely teaches the future psychiatrist the unity of mind and body, the interactions between organic and emotional factors, the importance of listening to a patient's complaints, and to see the patient as a member of his family or to recognize his aloneness in the world and its implications.

The general internship is not a waste of time for the would-be psychiatrist but a necessary learning and life experience. If we study the history of psychiatry, it becomes evident how inseparable psychiatry and medicine are and how this unity enables us to alleviate suffering always and to cure sometimes. If we want to retain our M.D. degree, we must earn it by remaining physicians who specialize in psychiatry.

MANFRED BRAUN, M.D.
New York, N.Y.

SIR: Dr. Engel, in his well-documented and lucidly reasoned editorial, deplores that "the American Board of Psychiatry and Neurology has decreed in effect that the traditional year's experience in the care of the sick, as exemplified by the internship, is a waste of time for the would-be psychiatrist."

This "decree" is strange doctrine indeed after all the years of growing emphasis on the holistic approach and when physicochemical, psychosomatic, and somatopsychic elements are increasingly being recognized as inseparably associated with functional and conditioning factors.

Nothing can take the place of the demands on clinical judgment and observation and of the dramatic human impact of medical and surgical wards. In his internship the medical graduate has the opportunity to evaluate the effects of medications; to see the physical effects of disease, the inherent trauma and possible complications of necessary surgery, and the possibilities of iatrogenic symptomatology; and to face firsthand the emotional reactions of patients to illness and the reactions of the patient's family and friends, as well as his own. If these matters are not of vital concern in psychiatry, what is? Where else can a young person feel and see them so vividly as in his internship, and with such comparative safety to his patients?

After over 40 years in the practice of psychiatry, I am convinced that a young doctor can experience in his internship the most valuable and informative period of his medical life and that there he can lay the best foundation for a career as a true doctor of medicine, whatever his specialty may become.

JOSEF A. KINDWALL, M.D.
Milwaukee, Wis.

SIR: Dr. Engel's final sentence concerning the need for action by those who feel that psychiatry should remain a field of medical specialists must be accented over and over again. It is good that Dr. Engel is willing to become the rallying point, since he is known and respected for his outstanding contributions to medical practice and education.

I wish to support fully Dr. Engel's objection to the general trend toward a reduction in the time and intensity of education for the future psychiatrist. The decision to remove the internship requirement will have a greater effect on psychiatry than on any other branch of medicine. As chairman of a department of psychiatry, I strongly feel that I should have had some input into this far-reaching decision, and I trust that others concerned with the education of future psychiatrists will attend to Dr. Engel's plea for action before it is too late.

JAMES L. MATHIS, M.D.
Richmond, Va.

SIR: Dr. Engel's editorial came as a breath of fresh air and good sense. I have been increasingly aware of the impending demise of psychiatry as I watch nonphysician therapists take over and as I listen to our young residents sophomorically disparage the medical model. There is no doubt in my mind that unless we identify ourselves as doctors of medicine first, we are doomed as a discipline.

I see no conflict between the medical model and the psychoanalytic, dynamic, behavioral, ego psychologic, or holistic models. The medical model, being biologic, does not preclude conceptualization of the mind in any of these accepted theories of human behavior.

Therefore, with Dr. Engel, I demand a return of the internship. I agree wholeheartedly that the care of the sick is our primary responsibility. I would like to add that our specialty probably demands more strength and maturity than any other. There is no substitute for the personal growth a young person experiences as he practices medicine as a fledgling and feels the weight of birth, disease, and death on his shoulders. These are the basic burdens of psychiatry, and the young psychiatrist must have handled them all before he is ready to handle his patients' problems. Ours is not work for weaklings or for the immature.

KERMIT H. GRUBERG, M.D.
Berkeley, Calif.

SIR: Dr. Engel made the strong point that the failure of psychiatry in its responsibility to medicine was most obvious in the decision of the American Board of Psychiatry and Neurology to abandon the requirement of the internship year. I agree with Dr. Engel in every particular. I further suggest that we consider taking a referendum among the members of APA to examine their opinions.

A. RONALD SORVINO, M.D.
Short Hills, N.J.

SIR: While I do not agree with every point that Dr. Engel makes, I do agree that the loss of the internship is a significant one in the education of psychiatrists. Although I have not had a chance to work with a psychiatrist or resident who has not had an internship, I consider my experience as an intern in a city hospital, and as a general medical officer in the Navy, to have been valuable. These experiences were important along three lines.

1. They helped me develop a working knowledge of medicine—exactly what it is to undertake the management of patients and to become familiar with using drugs and other physical procedures in surgery and diagnosis.

2. They helped me develop judgment about illness—about knowing how sick is sick, how serious a symptom is. This ability could only have been received through direct experience.

3. They helped me develop an understanding of doctors and hospitals and of how medicine is practiced in a hospital and in a community. I could not have been as valuable to physicians and nurses in other branches of medicine had I not had experience practicing medicine as they practiced it. In consulting with other physicians on the staff of nonpsychiatric wards, a knowledge of medicine is invaluable.

Perhaps physicians who choose psychiatry as a specialty will find other ways of gaining the valuable experience I have had as a physician. I believe, however, that we in the profession of psychiatry need to take a serious look at the consequences of the loss of a significant amount of medical experience prior to becoming a psychiatrist.

BEN KUHNER, M.D.
Denver, Colo.

Dr. Engel Replies

SIR: I am grateful to those who are sufficiently concerned about the issues raised in my editorial to address letters to me personally or to the Editor.

First, let me correct the misconception that I ascribe psychiatry's failures exclusively to the abolition of the internship. What I said was that this elimination has "opened the door widely to this decline"; the emphasis should be on the word "widely."

Dr. Eaton follows the posture of the Carnegie Commission that shortening the educational period is essential in order to solve the manpower shortage. Of all the fields, this argument is least credible in the mental health field. For if one accepts the argument that a medical background is not a prerequisite for all types of mental health professionals, then manpower needs can be better met by increasing the training and educational opportunities for nonmedical mental health workers. Places in medical schools should be reserved for those aspiring mental health workers who wish to function as physicians, and they should have a full, not a truncated, medical background. Those who would elect a highly specialized psychiatric-behavioral science track and would abjure other clinical work are dubious candidates for the M.D. degree. The answer lies more in upgrading the quality and prestige of the nonmedical mental health roles than in prostituting the M.D. degree, the attraction of which for some, I suspect, lies in the potential for higher income.

Drs. Eaton, Liptzin, and London all note the poor quality of some internships (to which one might add, of some psychiatric residencies as well). The new requirements expect the residency programs to provide the resident with some general medical experience equivalent to an internship, an illusory prospect at best. The net effect of this will only be that all psychiatric residents will have second-rate internship-type experiences. Obviously the answer is to bring about basic changes in the internship that will focus more attention on the patient and on his illness rather than merely on disease. But who is going to provide the inspiration and the foundations for such changes if not psychiatrists who have experienced these problems firsthand during their internship? This is part of the medical responsibility of those physicians qualified as psychiatrists.

Dr. Liptzin cannot be chided for being uninformed about medical educational patterns of 20 years ago. The fact of the matter is that today in many medical schools students are less, not more, actively involved in caring for patients. And this can only get worse as curricula are accelerated, the ratios of faculty to students and patients to students fall, and students enter their clinical work less well prepared in both basic science and clinical methods. Psychiatrists in particular should appreciate that their professional education is a developmental process. One becomes a physician by working with sick people and by evolving an identity that derives from the professional role. It is the active engagement in the care of the sick that, in fact, constitutes a vital life experience for the would-be psychiatrist. Those who do not feel comfortable in caring for the sick should perhaps have taken another pathway to reach their goal of being a mental health professional.

My questioning the wisdom of the hasty eradication of the in-

ternship is considered by my critics as standing in the path of progress. The decision to suspend the internship requirement was made by a small group of men with a minimum of debate and publicity (1, 2). This is neither scholarly nor democratic. There is legitimate ground for disagreement about whether the decision was good or bad, but there is no ground to defend the way in which the decision was reached. Responsible men would at least have attempted to evaluate the contribution of a medical education, including the internship, to the effectiveness of various types of psychiatric practice. They may well have discovered that for some roles no medical background is needed. Or could it be that the psychiatric establishment, all medical doctors, would rather compromise the meaning of the M.D. degree than relinquish their prerogatives, economic and other? I stand my ground: Psychiatry is the medical discipline concerned with mental health, and psychiatrists must be fully qualified physicians. The mental health field is too large and diverse to be dominated by physicians, especially ill-prepared physicians. And medicine is too important not to be served by psychiatrists who are anything other than highly competent physicians.

"NEW RESEARCH" PROGRAM AT ANNUAL MEETING

Four half-day sessions are being reserved at this year's annual meeting in Hawaii for "New Research" papers. The new research program, an innovation last year, presents "late developing and exciting research findings." Authors will have 15 minutes to present their papers, followed by five minutes of discussion.

Abstracts of papers submitted for this program must be received no later than March 1 by the Vice-Chairman of the APA Program Committee, H. Keith H. Brodie, M.D. APA, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. A complete text is not required. (Special abstract forms *must* be used; they are available from Dr. Brodie at the APA Central Office.)

BOOK REVIEWS

Treatment of the Borderline Adolescent: A Developmental Approach, *by James F. Masterson, M.D. New York, John Wiley & Sons, 1972, 280 pp., $13.50.*

In psychiatry, as in any field of scholarly endeavor, there appears from time to time an article or a book destined to have a significant and lasting effect in shaping subsequent developments within the area to which it addresses itself. At best, such a pivotal work systematizes and codifies clinical data, refines the work of diagnosis, subsumes within its substantives prior concepts once considered essentially unrelated, and provides impetus for further research.

Its unique contribution may comprise the delineation of a discrete, previously unrecognized clinical syndrome, like Kanner's description of infantile autism, or a comprehensive synthetic effort toward carefully documented systematization, like Bleuler's group of schizophrenias. In a very real sense Dr. Masterson's book combines both, central to which is the marriage of sedulous clinical description and a consideration of developmental processes viewed from the perspective of object relations. As such, the book has important implications for the mental health worker that transcend the adolescent phenomena and cases with which it is specifically concerned to also include earlier childhood, adult, and family psychopathology viewed from a developmental standpoint.

The author's delineation of the borderline syndrome of adolescence has proceeded from both theoretical and clinical considerations. It has resulted from a growing conviction, shared by others, that the so-called turmoil view of adolescence applies to but a minority of symptomatic adolescents and the fact that the symptomatic adolescents Masterson studied and treated had been suffering from psychopathology more severe than some sort of phase-specific and time-limited turmoil state or "adjustment reaction." Following consideration of these matters in the first chapter, the author proceeds to a detailed discussion of the complex processes inherent in normal separation-individuation, the etiology of the borderline syndrome based upon failure of these processes, the symptomatic-defensive features of the borderline adolescent, and the central role of chronic, unresolved "abandonment depression" in their evolution.

There then follows a wealth of case material, which, in both content and form of expression, illustrates the author's sensitive and comprehensive approach to the in-depth treatment of the borderline adolescent and his family. It includes definitive discussions of the residential milieu, individual psychotherapy, outpatient therapy, limit setting, joint parent-child interviews, and the use of school, recreational, and occupational therapies within a residential (inpatient) context designed and operated specifically to bring about the long-blighted processes inherent in parent-child individuation and differentiation.

Treatment of the Borderline Adolescent deals specifically with one symptomatically protean group of disturbed adolescents. However, it comprises in addition the most coherent and comprehensive statement to date concerning the intensive residential and outpatient treatment of adolescents, a masterly extension of the author's earlier work on the differential diagnosis of adolescent psychopathology, and a notable contribution to the growing literature on borderline and narcissistic personalities. Finally, it provides important insight into the ubiquity of failure of separation-individuation in the etiology of individual and family, and juvenile and adult, psychopathology. Few mental health workers can afford not to read, consult, and absorb the content of this notable contribution to the psychiatric literature.

DONALD B. RINSLEY, M.D.
Topeka, Kans.

Experimentation with Human Beings: The Authority of the Investigator, Subject, Professions, and State in the Human Experimentation Process, *by Jay Katz, with Alexander Morgan Capron and Eleanor Swift Glass. New York, Russell Sage Foundation, 1972, 1108 pp., $20.*

Recent headlines revealing that treatment had been withheld for many years from 412 syphilitic men jolted many of us from our comfortable nests of complacency, as did the report in 1963 that at the Jewish Chronic Disease Hospital in New York, cancer cells were injected into unsuspecting chronically ill patients. The latter case is included in Jay Katz's latest book, *Experimentation with Human Beings*, which is a major work in the medicolegal field and can easily be used as a keystone for research, interdisciplinary seminars, and lectures on the subject.

Writing in the casebook method, Katz has collected a wealth of material that includes newspaper and magazine articles, unpublished theses, reports of congressional hearings, and transcripts of testimony, as well as appeal-court decisions.

While the problem of organizing a work of this type is obviously difficult, the author and his assistants, Alexander Capron and Eleanor Glass, both young lawyers, have done a superb job. There are four main sections: An Introduction to the Human Experimentation Process, The Authority of the Investigator as Guardian of Science, Subject and Society, The Authority of the Subject as Guardian of His Own Fate, and The Authority of Professional and Public Institutions. Each section is divided into several chapters, each of which is introduced by brief comments and questions to be considered.

How much responsibility should experts have? What is "advised consent" for the African pygmy or the incarcerated criminal? What constitutes "harm"? Are the "obedience to authority" electric shock experiments ethical? How much information should be given to women for whom the Pill is prescribed? Should hybridizing experiments between human and animal cells be allowed? How much "freedom of choice" does one really have? How much freedom can we allow researchers for the purposes of progress? Can we secretly record juries? These are only a few of the questions that can be raised regarding the issues of human experimentation.

As our world becomes smaller and more affluent, we must look at these issues and make certain decisions or, at the very least, open our minds to a full consideration of the problems involved. As scientists dedicated to the betterment of mankind, we may find ourselves in conflict over many of the problems so clearly delineated in this book.

While this is not a book to read from cover to cover, the issues involved here are too important for our future to be

avoided or denied. We as psychiatrists are compelled to give serious thought to these issues. Whether we do formal research or not, we have voices that must be heard in many of the areas discussed in this volume. Every graduate school and training program should have a seminar on human experimentation, using this book as the basic text.

While Jay Katz and his collaborators do not give us the answers, they raise the questions and give us commentary and discussions as a foundation on which to begin our search. Each person must find his own answer, which can then withstand the challenge of self, profession, society, and others.

JONAS R. RAPPEPORT, M.D.
Baltimore, Md.

Comparative Psychotherapy: An Experimental Analysis, *by Adolph O. Di Loreto, Ph.D. Chicago, Aldine-Atherton, 1971, 309 pp., $9.95.*

This is a research project published in book form. Masses of data and statistical analyses are presented to support the contention that there is now available an adequate paradigm for research in psychotherapy; it includes measurable definitions of therapeutic techniques and their limits of applicability and quantitatively demonstrates therapeutic efficacy in delimited contexts. The research design requires simultaneous consideration of input, process, outcome, and follow-up variables. Unfortunately, the findings and conclusions of the author and his research staff may obfuscate rather than illuminate basic research questions relevant to psychotherapy's effectiveness. Nonetheless, there is a pioneering spirit that pervades the research effort and promises that this project will contribute to eventual research technology which will be able to delineate, identify, and quantify the necessary and sufficient conditions for effective psychotherapy.

This project seeks to compare the relative effectiveness of systematic desensitization group psychotherapy, rational-emotive group psychotherapy, and client-centered group psychotherapy in the reduction of interpersonal anxiety in separate groups of introverts and extroverts. It is comforting to me, however, to note that all three forms of therapy reduced anxiety more than did the therapies in either of the two control groups used. It is also of interest to note that in the two control groups, the placebo group in which there was contact between group members and research staff without attempted therapy showed more anxiety reduction than the placebo group where there was no contact at all with research staff. This suggests that outcome differences observed between the three treatment groups and the two control groups might be accounted for as resulting from a continuum of the degree of communicative transactional activity occurring between group therapists and group members, rather than as a function of the specific therapy used.

The obfuscation of the issues of therapy derives from the admitted fact that systematic desensitization was being compared as a form of therapy with client-centered and rational-emotive therapies in regard to anxiety reduction even though client-centered therapy and, to a lesser degree, rational-emotive therapy explicitly do not seek anxiety reduction as a primary goal, whereas systematic desensitization does focus explicitly on that target symptom. Anxiety per se is recognized in the approaches of client-centered and rational-emotive therapy as being to some degree desirable and necessary for growth, maturation, and risk taking.

Further obfuscation is derived from the study's implication that anxiety reduction should be a primary objective of all psychotherapy. It is well known that direct suggestion, hypnotherapy, and chemotherapy are probably more effective than either individual or group psychotherapy when the primary goal of the intervention is anxiety reduction. The usual goals of psychotherapy are more ambitious and include general symptom relief, improved social adjustment, maturation, and heightened autonomy and creativity. Of course, this should not be the basis for faulting this research project, which focuses entirely on the objective of anxiety reduction as the basis for comparing the three therapy models.

The book contains critiques by representatives of each school: Albert Ellis for rational-emotive psychotherapy, Alan Goldstein and Joseph Wolpe for systematic desensitization psychotherapy, and Angelo V. Boy for client-centered psychotherapy. They all make the point that although the study purported to compare these three therapies in "pure" form, this in fact was not done. The research design did not control the problem that the so-called schools of psychotherapy are hardly mutually exclusive in their theories, techniques, and models; there is considerable overlap among them.

The fact that one of the control groups had contact with research staff without therapy and still showed greater anxiety reduction than the no-contact group suggests that the study may primarily reflect the nonspecific effects of psychotherapy on anxiety. That is, independent of the specific model and techniques used in psychotherapy, the therapeutic situation and experience itself will decrease patients' anxiety.

This study does not address itself to the overriding question of complicating side effects of directive therapies such as systematic desensitization and rational-emotive psychotherapy: namely, that the therapeutic gains invoked by authoritarian, directive, structuring, manipulative, pedagogic, and avuncular therapists all exact a high price. Directive therapies foster and reinforce dependency, activate fusion fantasies, and deprive patients of the opportunity for achieving the more long-lasting growth and maturation that could occur in a therapeutic relationship that is egalitarian, nondirective, nonauthoritarian, and intimately communicative. However, despite its shortcomings, I recommend this book highly for the serious student of research methodology in psychotherapy.

Portland, Conn.

Modern Perspectives in World Psychiatry, *edited by John G. Howells, M.D., D.P.M. New York, Brunner/Mazel, 1971, 728 pp., $25.*

The complexities of a holistic approach to the integrated understanding of human behavior are amply demonstrated by the disciplines and subdisciplines of the life sciences represented in this volume. The title of the book well defines the scope of its contents, for the editor has selected authoritative presentations on a wide range of basic and applied fields of study by authors who are internationally eminent in their chosen specialties.

The book is divided into two sections. The first deals with scientific knowledge and the second with clinical concepts and practices representing the major psychiatric approaches. Each author has selected the most significant material in his own field, so that each chapter is an extensive review of current knowledge in that area and gives the reader an up-to-date overview of contributions pertinent to the field of psychiatry.

That the advances in modern psychiatry have come through developments in many other fields is reflected in the diversity of subjects covered in the volume. In the first section these range from the biochemistry of mental illness to the phenomena of hypnosis, from cytology of the nervous system to body image

and corporal awareness, and from the neurophysiological basis of thought to the significance of nuclear sexing.

Some of the chapters report on basic research in a number of highly specialized fields. They are, however, presented in language sufficiently nontechnical that most of the material is communicated to the nonspecialized reader in a clear and understandable manner. However, more than a superficial interest in and acquaintance with the subject matter is sometimes necessary.

The editor has been most successful in bringing together such disparate spheres of scientific inquiry and placing them in order so that there is a sense of relatedness.

The second section is a valuable anthology of the major modern psychiatric systems and their application in many countries—Morita therapy in Japan, existential analysis in Switzerland, Pavlovian theory in Russia, psychoanalysis in the United States, family therapy in Great Britain, and so forth.

With authors drawn from many countries, the volume indeed places in perspective the particular approaches prevalent in different nations. For American psychiatry, with its emphasis on psychodynamic formulations, the importance of the contributions of physiological knowledge and concepts to the behavioral sciences provides an enlightening balance.

While there has necessarily been some selectiveness, each account deals with recent formulations and emphases in its subject matter. Appropriately, the first chapter in the second section deals with the contributions of clinical psychology to psychiatry. It is written by an eminent British psychologist whose scientific skepticism about psychiatric systems in general and about analytic psychotherapy in particular is well known to clinical psychologists in the United States.

Equally appropriately, the penultimate chapter deals with transcultural psychiatry—a new and emerging field of study that has the potential for many contributions to fundamental knowledge about human behavior.

This volume is not intended to be a textbook in the usual sense of the word. It collates knowledge from many scientific fields significant to the development of modern psychiatry and, together with the extensive bibliographies that accompany each chapter, will serve as a useful reference for further study. For any psychiatrist who wishes to be well informed regarding modern-day formulations of psychiatric concepts, this volume will be an important source in broadening and deepening his appreciation of recent thinking in the field. The psychiatric resident should find this work a first-class educational instrument in obtaining basic information about the current psychiatric concepts that prevail in different parts of the world, and it should broaden his professional horizons at an early stage in his professional development.

The implicit message of the volume is that human behavior is now viewed in the context of many valid frames of reference and that differences in advocacy arise from the emphases, biases, and philosophies of the proponents of specific systems. This conclusion comes through because of the objective way in which each author offers his contribution.

Crises of Family Disorganization: Programs to Soften Their Impact on Children, *edited by Eleanor Pavenstedt, M.D., and Viola W. Bernard, M.D. New York, Behavioral Publications, 1971, 103 pp., $5.95.*

This excellent and most interesting book is a compilation of eight papers presented at the New York State fifth biennial divisional meeting of the American Psychiatric Association in 1967. The focus of the book is on the lack of integration between the hospital staff caring for the psychotic parent and the community agencies, which most of the time are not alerted to the plight of the patients' families or to the problems of the discharged patient.

The editors welcome earlier hospital discharge for psychotic patients and the reduction of the social breakdown syndrome that often results from prolonged custodial hospitalizations. However, they are also very aware of the harmful psychological interactions that result when parents and their children are reunited at home without proper hospital planning for the discharged psychotic parent and the readying of the home situation with community support. They stress the lack of a treatment plan, both for the discharged psychotic parent who frequently returns home without community resources to make his job easier and for the children returning to the home without proper community help for easing them back into a most difficult situation. The editors identify the types of crises that should be of concern to psychiatrists as far as children are concerned, and they strongly urge community help—specifically, homemaking services, infant-child centers, later-age child-care centers, and especially continuing psychiatric supervision of the discharged patient.

The editors strongly urge psychiatrists to develop "binocular vision, so that they might see, instead of separate images of the sick parent and the young child, those two images fused into a view of their interactions in the total family context."

In her paper "Meanings of Motherhood in a Deprived Environment" Eleanor Pavenstedt discusses the health center and family health groups that serve families living in the Columbia Point Housing Project in Boston. The groups consist of a pediatrician, an internist, a social worker, two public health nurses, and a nonprofessional family health aide. Much emphasis is put on training mature women from poverty areas in healthy child rearing, child care, and elements of nursing and child psychology so they can then go into the neighborhood and make the bridge between the health center and the families living in the area. Dr. Pavenstedt questions any reliance on placement away from the home as a treatment measure for children, since in so many cases the mothers who are ill are from an orphanage or foster home placement themselves. She feels these mothers are "extremely fragile, having little energy to cope with their family, and being chronically depressed, or both."

In the last paper, "Parental Incapacity and the Welfare of Children," Roberta Hunt cites the chronically overcrowded conditions of the shelters the community maintains to receive children caught in a child-care crisis situation. There is the chronic inability of social service agencies, both government and voluntary, to meet the needs of families where there is a breakdown in parental capacity. The major thrust of the study is to prevent foster care placement, which unfortunately is done too often on a crisis basis and much too late—often after the family deterioration is advanced and serious, and after possibly irreversible damage to the child has already occurred.

A plea for responsible casework planning before the child is removed from the home and the establishment of comprehensive services to assist the child in the family led to some rewarding changes in the New York City setup. A nighttime and weekend emergency child welfare service telephone, with "night watchers" or child sitters to stay with the children during that crisis period when the parent is removed from the home, has at least cushioned the trauma of the child. Homemakers went to the family immediately so that the child could remain at home in familiar surroundings, near his school and friends,

and then, it was hoped, receive long-term supportive services in the community.

This book emphasizes that there is *no* such thing as an isolated psychiatric illness; the reflection of such illness is seen within the entire family. It is urgent that agencies, hospitals, and all the professionals and paraprofessionals involved be aware of the entire social situation and problems inherent therein.

BENJAMIN H. BALSER, M.D.
New York, N.Y.

The Drinking Man, *by David C. McClelland, William N. Davis, Rudolf Kalin, and Eric Wanner. New York, Free Press (Macmillan Co.), 1972, 386 pp., $10.*

This technically exhaustive book reports the results of a ten-year, NIMH-supported study of why men drink. The authors explore the deeper motivations for drinking below the surface explanations of "to quench a thirst," "to be social," or "to celebrate an event." They examine the physical, mental, and emotional states that influence how much and how often a man drinks. They found, for example, that a group of men drank more when a female singer was part of a party than when there was no woman present. The setting for alcohol-induced fantasies of power and sexual prowess encouraged heavier drinking.

The authors' conclusions—arrived at empirically and supported by observations relating male drinking to the effect of alcohol on fantasy, folk-tale themes, cross-cultural influences, and the individual needs of heavy, habitual drinkers—suggest that men drink because alcohol gives them a feeling of power. Their studies led them to reject the currently popular "dependency" theory of alcoholism in favor of a "power" theory of men's drinking patterns.

Another effect of alcohol on the men studied was a tendency to "space out time concern," resulting in their ignoring the need to get back to work or to get home and thus prolonging the drinking. In college men, the feeling of power and sexually aggressive fantasy was exemplified by the "stud" syndrome produced by alcohol. The authors observed that many heavy drinkers were characterized by strong concerns for personal power, aggression, prestigious possessions, and dominance. They suggest that therapy might be directed toward substituting real power for alcoholic fantasy. Such satisfactions as helping people, holding office in worthwhile organizations, sports, or succeeding in one's chosen work can replace alcoholic pseudo-power illusions.

In certain societies the collective fantasy of folk tales endorses heavy drinking. In some societies, where the masculine image is diminished, such as with the Irish and disinherited Indians, and with men in small Mexican villages and black men, where outlets for socialized power channels are often blocked, men are prone to heavy compensatory drinking in order to attain the temporary illusion of power. Arabs, on the other hand, have a high demand and support for the masculine role and thus have little need for drinking. Some men, as they age and lose power, turn to alcohol to at least retain a feeling of power.

The authors suggest that men do not drink primarily to reduce anxiety, since men in cultures with a high tradition of anxiety drink less, not more. They also see little evidence of increased dependency concerns in heavy drinkers, who often express counter-dependency aggressive behavior.

The authors realize that many of their concepts are innovative and radical and not entirely supported by scientifically sound evidence. Their ideas regarding male drinking, however, obviously contain much truth when one stops to think about it, and this book represents a milestone along the path to a better understanding of alcoholism. One cannot help but wonder, however, why women drink. Although this book does not touch on the subject of female alcoholics, perhaps they also drink to attain a feeling of power.

FREDERICK LEMERE, M.D.

The Psychoanalytic Process: A Case Illustration, *by Paul A. Dewald. New York, Basic Books, 1972, 655 pp., $15.*

This is a somewhat unusual book in that the author, a training psychoanalyst, reports in some detail a more or less verbatim outline of his analysis of a young married woman. The psychoanalytic hours are reported in terms of the patient's statements as well as the analyst's responses. This is followed in each chapter by a discussion of what had transpired during the hour and why the analyst and the patient reacted as they did.

The patient would appear to have had a mixed psychoneurosis, as the author describes. She had problems with eating, phobias, and depression, and sexual difficulties. She obviously was an intelligent young woman who had realized that her previous, more brief therapy was insufficient and that she needed more intensive treatment. She faced that problem of whether or not to undertake psychoanalysis and, if so, how to pay for it. Nevertheless, as the author points out, she made her decision and went ahead with analysis, which turned out to be reasonably successful.

Once treatment began, the patient demonstrated many of the qualities often seen in analytic patients and even in those in other types of dynamic therapy. She feared losing control of herself. She resented the analyst's neutral stance, and for quite some time she remained convinced that he would react as others had done in the past. She did develop a transference neurosis, which she was able to understand and work through.

This young woman had been raised in a family in which there was parental strife, with the father having affairs. The patient herself had had a sexual experience with an uncle at an early age. These and other factors led to some of her oral and oedipal problems. Even though she had difficulties from all levels of psychosexual development she would probably be considered primarily a hysteric, and one with reasonable ego growth. She made good use of the analysis, and the author is careful to point out that, as such, she responded better than many patients do to this type of treatment.

All in all, this is a unique book in that it does report in some detail the contents of a particular psychoanalysis. It has the added value of having the author's contributions regarding his own reactions, whether they be realistic or countertransference in nature. Perhaps one drawback is the difficulty in putting into written words those things which were verbalized spontaneously. For example, the author frequently uses the word "detail," and in print this obviously sounds more formal and less relaxed than it must have during the analysis. He also has a specific way of ending each hour, which at times sounds rather abrupt and unfeeling, although one cannot tell from merely reading the book.

I recommend this book to any serious student of psychoanalysis and of psychoanalytic concepts. It answers at least in part one of the frequent criticisms of analysis, namely, that no one except the analyst and the patient really know what is transpiring. Its primary problem is that it describes a reasonably

"good" patient and therefore does not contain as many of the difficulties usually encountered in analysis as it might. The author is quick to admit this. Nevertheless, the book is to be recommended for anyone interested in how a psychoanalysis may go and in some of the factors involved in how the analyst handles his patient.

STUART M. FINCH, M.D.
Ann Arbor, Mich.

Principles of Child Psychotherapy, *by Donald J. Carek, M.D. Springfield, Ill., Charles C Thomas, 1972, 218 pp., $10.75.*

Thirty-one years ago F.H. Allen commented on "the somewhat sparse literature on psychotherapy with children" when he wrote a book on this subject (1). Carek now finds:

> The literature on child therapy is lopsided. First, therapy of children is overshadowed by literature on child psychoanalysis. Second, the existent literature leans toward establishing more securely a premium on intensive therapy which is akin to child analysis. There is a need for delineation of a broader view of child therapy and all it entails.

He also points out:

> Though it is understandable that child therapy is and will be compared to adult therapy, to build a conceptual model on such comparisons does have drawbacks.... Unfettered of limitations inherent in adult-child therapy comparisons, hopefully child therapists might become less obsessed with worrying about parameters to be used in child therapy. Hopefully they then might get more to the business of considering child therapy in its own light. Looked at in another way—in a developmental fashion—the child therapists need to let the identifications with adult therapy give way to establishment of an identity in child psychotherapeutic work.

With these points as a broad base, Carek proceeds to develop a credible report of operational, eclectic approaches to the developmental and situational problems of childhood. He points out that "the bulk of child therapy is crisis intervention in the true sense of the word." Like E. Singer (2), he believes that "it would seem more reasonable to put the emphasis in therapy on awareness rather than on insight, 'the awareness of inner situations (and outer situations) which have been dissociated in an attempt to deny them.' To some, such awareness may approximate or even be synonymous with insight." He goes on to say, "One would reasonably say that those involved in helping a child develop adequately will need to think in terms of helping a child remain or become accessible to his internal forces and to those environmental forces that ordinarily enhance his personality development."

Characteristic of this book is the plea for moderation in implementing dichotomous concepts where neither extreme is completely tenable in all cases. For example, in considering the recurrent nature-nurture controversies, the author proposes: "Hopefully the therapist remains mindful of the complex interactions involved at a multitude of levels so that he does not feel compelled to take sides in fruitless controversy bred of simplistic reductions." Carek is particularly adept at the wry questioning of some erudite interpretive trends, when situational factors are obviously more contributory to the content of a child's productions than are unconscious conflicts.

Especially interesting is the author's awareness of growth potential as a significant factor in effective therapy with children. He agrees with others who feel that one "should resist the tendency to become the proud parent who may then unconsciously wish to hold the child through subsequent development." As he points out in a boy's case he reviews briefly, a particular age-specific conflict "was not one to be resolved in therapy but a conflict with which he needed to tussle and work out over an extended period of time during the long span of adolescence within the multitude of his everyday interactions." Carek recognizes that "maturational pull" enhances the effectiveness of therapy with children, and he defines this factor as "an inner directive force, derived both from innate, constitutional factors and from internalized environmental expectations." In these frames of reference he can reasonably state: "In effect, psychotherapy is to help remove the roadblocks—if they are conflicts, to help resolve them—that interfere with the child's dealing or coping with his developmental task."

Many will disagree with some of Carek's theses. Nevertheless, this is a book that needed to be written, and it deserves careful reading by anyone concerned with the developmental problems of children.

Two Gentlemen To See You, Sir: The Autobiography of a Villain, *by Victor Carasov. New York, Taplinger Publishing Co., 1971, 191 pp., $5.50.*

This book is a story of man's inhumanity to man, a story of the cursed life of a man who seemed to have known himself, but who, because of utter deprivation, rejection, and an almost uncontrollable need for seeking misery, has lived far more of his life within prison walls than outside. His name—Victor Carasov—may be unimportant, but his description of his mutilated life is a significant document in the annals of crime.

The author was born in England. The divorce of his parents, an unhappy combination of a Russian father and an Irish mother, resulted in the complete rejection and neglect of their son. He himself, though, may have had some of the seeds of self-destructiveness within him to cause him to turn his life into one of persistent crime. From an early age he learned to steal, burglarize, and cheat. While he claims that he tried to earn an honest living every time he was released from prison, all his efforts came to naught.

Carasov did not find redemption in a world that had completely rejected him. Yet he has insight enough when he says:

> Above all, I must put it on record, *most of my experience was brought upon myself, by myself....* I spent nearly two years of the four-year term, disturbed my mind and my nervous system for years and years. Also, the *anger*... the *rage*... the *resentment* engendered *there* was the *motivating force of many of my subsequent crimes.* In other words, I later *hurt people* in the free world as a kind of *transference of all that violence I felt* towards the Broadmoor personnel... at least, that part of it with which I was all too familiar (p. 59).

Shortly thereafter he was accused in Broadmoor Prison of threatening the prison staff, and after due warning, he was attacked by a fellow inmate. Carasov, however, was able to control himself, for which he was commended, and because of his good behavior, he was transferred to another ward. However, there he got into a fight with a man who had made advances toward him. He was then put in canvas and in solitary confinement, with the admonition that "if he continues to attack others he will be put in canvas for the rest of his time."

Following these experiences, Carasov got the idea of writing the story of his life. He talked with a Mr. Gollancz (a publisher, recently deceased, who was known for his interest in social and criminal problems), who gave him pen and paper for writing his story. However, it took some time because Carasov did not really give up his criminal way of life but continued as a habitual thief in and out of prison.

On the outside he did not live a chaste life. There was sex; as he describes it: "Not only did I have to make love to the mistress, but to the maid also, which was not entirely to my taste. It smacked too much of cheap, cheap orgy .... Funnily enough, though I am a bit of a tramp, a bit of a bastard in some ways, there are some things I *won't do* and this *maid* and *mistress* thing I *did not like*" (p. 96).

As the book ends, Carasov has been incarcerated at the "new look" prison, Blundeston, for four years, waiting for parole. Now, all in all, he has spent 50 of his 65 years in a succession of prisons, unrehabilitated.

Two Gentlemen To See You, Sir is written with some humor, some self-understanding. Even if at times Carasov's description of his escapades becomes boisterous, repetitious, even boring, he has succeeded in bringing forth a frightening, yet accurate picture of English prison life—which is not unlike life in our own prisons. His book is one more page in the myth of misunderstood rehabilitation. Yet one is compelled to wonder whether benign treatment—provided our prisons could furnish it—would be more effective in rehabilitating prisoners. Prisons brutalize the correctional officers and the inmates. To my mind, only 15 to 20 percent of the people incarcerated ought to be kept within prison walls because of their danger to society and to themselves. The rest ought to be treated in rehabilitation centers, if such institutions could be established.

Although we may not think that humanization of our prisons would reduce crime, our belief in human individual dignity must be the guiding light for the handling of criminals.

DAVID ABRAHAMSEN, M.D.
New York, N.Y.

Progress in Neurology and Psychiatry: An Annual Review, vol. XXVI, *edited by E.A. Spiegel, M.D. New York, Grune & Stratton, 1971, 559 pp., $29.95*

This twenty-sixth edition of Dr. Spiegel's well-recognized annual book makes a noble attempt to reach its objective: a survey of progress in the closely related fields of neurology and psychiatry. As noted in the preface, the increasing output of the world literature necessitates a periodic selection of some subjects for review. Particularly fortunate selections for the current edition are the clinical subjects of ophthalmoneurology, neuroendocrinology, and group psychotherapy.

As usual, the book is divided into the four sections of basic sciences, neurology, neurosurgery, and psychiatry.

In the first section, neuroanatomy, biochemical aspects of neurophysiology, regional neurophysiology, neuropathology, and neuropharmacology are covered with voluminous references to the literature. These chapters provide the clinician with a valuable survey of new developments in these basic sciences.

In the second section, clinical neurology, otoneurology, neuro-ophthalmology, epilepsy, neuroendocrinology, the autonomic nervous system, cerebrospinal fluid, and neuroradiology are covered in an admirable fashion. The survey of these subjects includes comprehensive references to the literature.

In the next section, which deals with neurosurgery, attention is given to the peripheral nervous system, central nervous system, trauma, and brain tumors. These chapters are somewhat limited in their survey, but references to the literature are adequate.

The section on psychiatry is divided into the subjects of clinical psychiatry, criminal psychopathology, child psychiatry, family therapy, alcoholism, psychosomatic medicine, psychoanalysis, group psychotherapy, drug therapy, and occupational therapy. In all of these subjects sources for information are obtained from the many references to the literature. The chapters on clinical psychiatry, family therapy, and drug therapy are especially commendable.

The contributors to this comprehensive volume of 28 chapters consist of a representative group of specialists in the basic science and clinical aspects of neurology and psychiatry. The book primarily deserves recommendation for its reference to approximately 5,000 papers that have been reviewed by the contributors. An index completes the volume.

NATHAN S. SCHLEZINGER, M.D.
Philadelphia, Pa.

Psychiatric Disorder and the Urban Environment, *edited by Berton H. Kaplan, with Alexander H. Leighton, Jane M. Murphy, and Nicholas Freydberg. New York, Behavioral Publications, 1971, 310 pp., $12.95.*

This book summarizes the proceedings of a seminar series on psychiatric disorder and the urban environment held at Cornell University under the guidance of Alexander H. Leighton. The participants included Lloyd Brightman, Isidor Chein, Catherine Fales, Harold Feldman, John R. P. French, Jr., Nicholas Freydberg, Herbert Gans, John Gulick, Paul V. Gumpl, John S. Harding, Lawrence E. Hinckle, Jr., Laurel Hodgden, Raymond Illsley, Mirra Komarovsky, Thomas Langner, Dr. Leighton himself, Stanley T. Michael, Jane M. Murphy, and William F. Whyte. This distinguished cast was charged with the task of considering various alternatives for studying the urban environment's influence on mental health and mental illness.

Kaplan provides the following rationale for the publication of this book:

> a. To preserve the exchange of ideas that appeared most relevant to the future development of the field of social psychiatry; b. to stimulate the clarification of ideas on social processes and mental illness; c. to preserve some worthwhile ideas and information that otherwise would be fugitive; and d. to preserve selected commentaries that illustrate how experienced investigators have asked various questions on studying the impact of social process on mental health.

To achieve these goals Kaplan has retained some extended excerpts from the actual seminar conversations, but he has also provided orienting papers and brief summary statements of much longer seminar discussions.

The book is organized around Alexander Leighton's theory

of the relationship of mental illness to social disintegration. While the book is devoted primarily to questions of procedure, research design, and methodology, it also contains material of more conceptual and theoretical interest.

Despite Kaplan's thoughtful and skillful editing, the volume suffers from the problems that seem to be inevitably inherent in such seminar proceedings: The participants were uneven in their preparation, and few presented their ideas with either the cogency or precision that characterizes their more formal publications. To be sure, there is something to be said for preserving the give-and-take, preliminary quality of seminar exchanges, but in this case these exchanges are not particularly exciting. There are glimpses of confusion, acrimony, humor, and the sense of discovery, but too few to preserve the excitement of a seminar.

What remains is a portrait of competent scientists saying interesting things that are relevant to the underlying theme but not presenting formal methodological innovations, new data, or new conceptual positions. Part of the problem may lie in the fact that Leighton's disintegration thesis has been well known for more than a decade, and much of the material in this book recapitulates what has long been common knowledge for any professional interested in this area. It could not have been easy for the participants to be creative about an idea that has been with us since Durkheim.

Although these faults make much of the book unrewarding reading, one should not conclude that the book is without redeeming qualities. It does accomplish, to some degree, each of the four objectives Kaplan set for himself. The serious student of social psychiatry will find intriguing and informative passages that will repay him for reading carefully what he might at first glance be tempted to set aside. Furthermore, the Leighton thesis that mental illness is a product of social disintegration is of such fundamental importance for our assumptions about the nature of man, society, and the etiology of mental illness that any inquiry into its viability must be valuable.

I wish that the seminar participants had challenged the basic assumptions of this thesis with empirical data (for I believe that there are both epistemological and empirical grounds for urging its modification), but I appreciate their effort to deal with methodological issues that relate to it, just as I commend the editor for his serious efforts to create a book out of much less than a book. He does not fully succeed, but he nevertheless brings together enough valuable material that the volume will be of interest to social scientists and psychiatrists who wish to think further about social disintegration and mental illness.

ROBERT B. EDGERTON, PH.D.
Los Angeles, Calif.

Perspectives on Violence, *edited by Gene Usdin, M.D. New York, Brunner/Mazel, 1972, 161 pp., $7.50.*

Perspectives on Violence consists primarily of papers on violence, written by a historian, a social psychologist, an anthropologist, and a psychiatrist, that were presented at the 1971 annual meeting of the American College of Psychiatrists.

Dr. Usdin's excellent preface and Dr. Henry Brosin's introduction anticipate the contributors' conflicting views of the origins of man's violence and its solution.

Professor H. Stuart Hughes gives a historian's critique of violence. Taking a long view of revolutions, he questions the extent to which they have marked a change for the better in human events. The expected alterations are not always forthcoming, and "their accomplishments may seem incommensurate with the sufferings they have entailed." He suggests that revolutions may be significant not so much for what they actually do as for the legend that gathers around them. According to Hughes, students consider revolutions and civil wars to be justified, while their professors, on the contrary, find the rare examples of the moral application of violence in wars of national self-defense (like the Allied effort in World War II). The students see "acts of violence they approve as effecting some beneficent change. The professors justify the violence they approve as preventing a greater evil."

Besides the ordinary legal processes, Hughes sees only two alternatives to force: disciplined, mass nonviolence and individual secession. The first has been successful in some instances (e.g., in India) because of an awareness that the established powers lacked the determination to apply counterforce with utter ruthlessness. (Where established power has not hesitated and there has been no hesitation in suppressing dissent at all costs, mass violence has seldom been attempted.) The second alternative suffers from severe limitations and does almost nothing to affect the course of events.

Dr. Nevitt Sanford discusses the sources and remedies of collective destructiveness. He attributes group murder, enslavement, torture, and reduction of dignity to a belief that what is done is right or necessary and that the victims are less than human or beyond the pale. He refers to such social destructiveness as sanctioned or legitimatized evil. Ordinary people who may even be opposed to group destructiveness surrender their individual consciences in favor of the organization's morality and contribute merely by "doing their jobs." Sanford believes that aggression, including its violent manifestations, is provoked by frustration. It is not inborn but is generated out of experience and learning—primarily in childhood. It involves a projection of one's own badness onto others. Destructiveness may also be carried out by people who are merely responding to the guidance or commands of superiors. Promoting universalism in the human community and wholeness in the individual personality are suggested as ways of preventing collective destructiveness.

In his presentation of anthropological perspectives on violence, Dr. Wilton S. Dillon emphasizes the interplay among obligations, hostility, and dependence as precursors to violence and the role of gifts in peace keeping, as observed in studies of various South American and Pacific Island cultures. He looks to the production of a diagnostic tool or a social indicator of potential violence as one way of controlling violence. It would "detect the stresses and strains between individuals or groups when donors and recipients" fail to reverse their roles and fail to find exchange commodities to which both attach value.

He warns:

> The best-intentioned public servants, editors of the mass media, and legislators seem innocent about the hazards of charity, pity and guilt. Unless accompanied by an attitude that the recipient has something to offer, that he dislikes being on a permanent dole, the "donors"... court new opportunities for social conflict when they act benevolently and then expect, in return, gratitude and docility.

He urges a search for operational meanings to the following three prescriptions: Leadership consists of discovering the means by which individuals (or nations) feel indebted and can offer their gifts toward a common good; the importance of functional reciprocity in human organization; and the importance of play, humor, and ceremony in human interaction.

The psychiatric approach is presented by Dr. Charles A. Pinderhughes. He focuses on the roles of projective identification

and paranoia in violent interactions and the underlying mechanism in which the enemy represents a renounced and projected part of the self, which in the moment of violence is perceived as totally evil. He believes that as long as we engage in introjective identification, which is the basis of group formation, and employ projective identification with others, we will have uncontrolled group-related paranoia and violence in human intergroup behavior.

The book concludes with excellent discussions by Drs. Howard P. Rome and Louis J. West.

The various approaches to the subject of violence contained in this book clearly illustrate the complexity of the problem, and it is in this that a major strength of the book lies. It is thought provoking and a good beginning for those who are interested in understanding this important problem that somehow keeps coming closer to all of our lives.

Mental Illness in Childhood: A Study of Residential Treatment, *by V.L. Kahan. Philadelphia, J.B. Lippincott Co., 1971, 207 pp., $10.*

Mental Illness in Childhood details an excellent research and treatment program carried out in the early 1960s at West Stowell House, an English residence for severely disturbed children. The book is especially significant since it describes in a reproducible manner a program that was well integrated into a total system of services and carried through within tight budget limitations. A humane ideal of "child centered intensive care" underlies policy in this project. Dr. Kahan believes that good relationships are necessary for therapy of any type, that most disturbed children have basic problems with relationships, and that they function within a continuum of personality strengths varying from normal to maladjusted to psychotic.

About 30 children at a time were treated at this unit in "family groups" of ten, with a round-the-clock staff-to-patient ratio of no less than two to eight. Living quarters were homelike, regressive behavior was permitted, and nurturant staff responses were encouraged. Play, special education, and psychotherapy were individualized. Drug therapy was minimal. Parents were offered help rather than directions or blame. The book is valuable alone as a manual for practical residential treatment.

Careful study was made of all 71 children seen during the six-year program; diagnostic evaluations were performed, background material was gathered, and a symptom checklist was kept. Most findings appear in tables under four categories of patients: psychotic, psychotic and severely retarded, disturbed in reaction to subnormality, and conduct-disordered. However, numbers were too small for statistical validity, and there was no normal control group. Dr. Kahan's discussions of results, however, are a lesson in clinical observation. Motor abnormalities, speech, sensory experiences, destructiveness, and mannerisms are each considered in detail, and then some conclusions are cautiously made. Mannerisms in psychotic children, for example, appeared to be a valid diagnostic sign, while hyperactivity was nonspecific. Most psychotic patients showed evidence of brain damage. Family interactions were thought to play an important role in severe pathology, most often as an irritant to the patient's congenital vulnerabilities.

Follow-up of patients for social rehabilitation indicated results comparable to those of other good centers. Fifty-seven percent of the psychotic children and 78 percent of those with behavior disorders, for example, showed "much improvement." Overdependence, passivity, and indifference to adults reduced favorable prognosis. Retarded children did more poorly in this setting. Sixteen detailed case histories in the second half of the book give the reader a feeling for clinical process.

This book needs to be taken seriously. Residential treatment, after all, is a court of last resort for any system of family or child psychiatry. *Mental Illness in Childhood* is recommended as a reference for teaching about childhood psychosis and for those engaged in planning treatment units.

OFFICIAL ACTIONS

Position Statement on Community Mental Health Centers

This statement was approved by the Board of Trustees of the American Psychiatric Association at its April 29–30, 1972, meeting, upon recommendation of the Council on Mental Health Services. It was prepared by the Task Force to Develop a Position Statement on Community Mental Health Centers.[1] *The Assembly of District Branches endorsed the statement at its November 3–5, 1972, meeting.*

Psychiatry, because of the social aspects of many of the problems it undertakes to remedy and because of its comparatively long and close association with government, has already had both the privilege and the burden of attempting to pioneer comprehensive health services through the vehicle of the community mental health center. The American Psychiatric Association strongly supports the purposes of community mental health centers: 1) to provide ready access to mental health services and related medical and psychosocial care for all persons within a given population who need such services, and 2) to offer a model on which to build in the evolutionary process of constructing a more effective national health system.

The centers are flexible, evolving modalities that are adaptive to cooperative arrangements with comprehensive health centers and broader human services. They operate on a "catchment-area" principle which dictates that they shall assume responsibility for meeting the mental health needs of a defined population without discrimination of any kind and with emphasis on preventive and health maintenance services, as well as on treatment of illness and rehabilitation of patients. This obligates them to render direct and indirect services for a far greater number of persons than was formerly possible, to develop new treatment strategies for categories of patients formerly considered "poor candidates" for therapy, to eliminate long waiting lists, and to develop continuity among service elements.

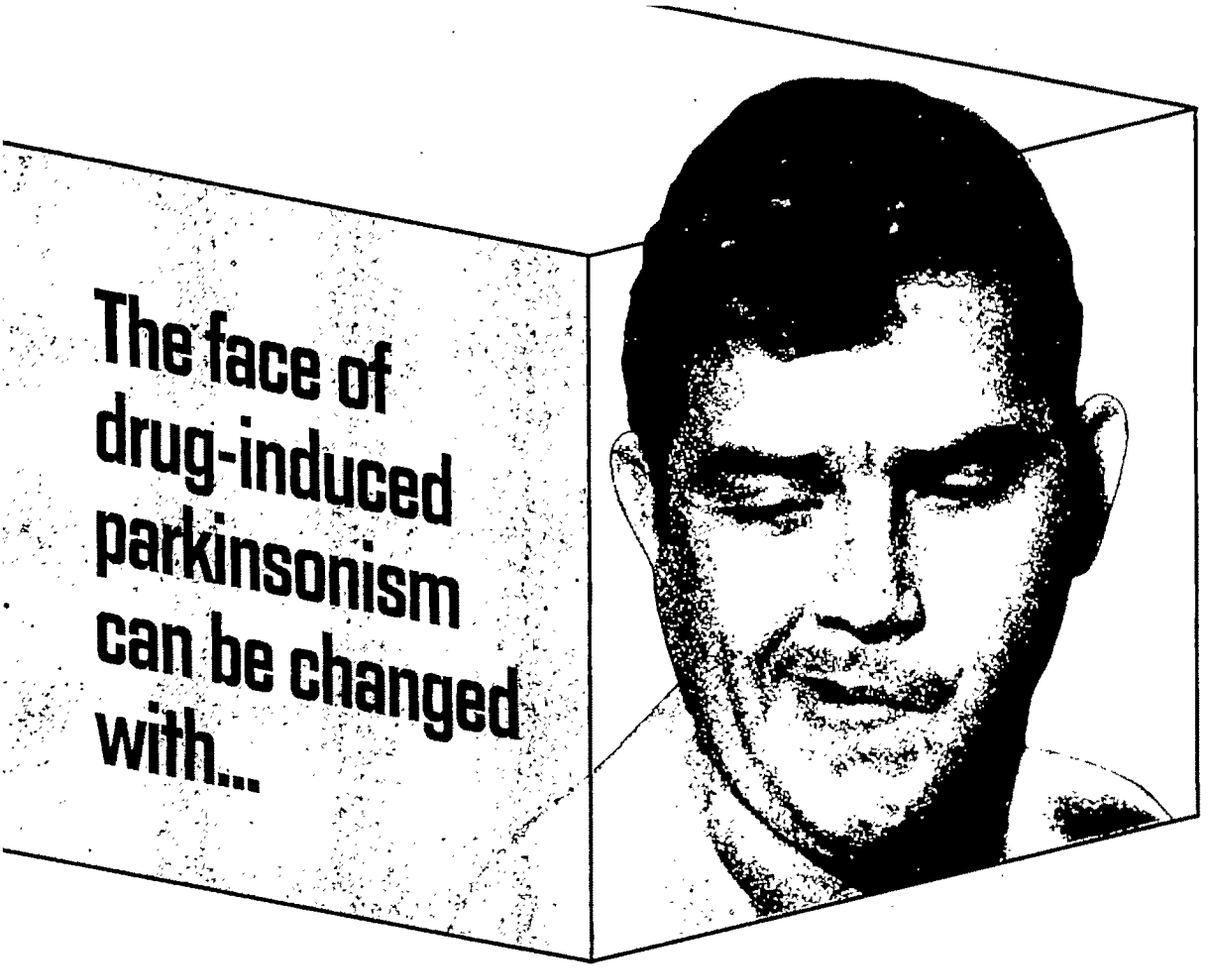
The integration of services, as among community mental health centers and public and private psychiatric hospitals, must be planned with great care so that the network of mental health services in a catchment area will be rationally organized as a continuum. A key responsibility of the centers is to assist in the development of active treatment and rehabilitation programs in psychiatric hospitals, to obviate the need for hospitalization whenever possible, and to assume immediate responsibility for services to patients who have been hospitalized and have returned to the community. This purpose would be ill served if the centers were to cope only with the acute or most highly treatable patients and were to transfer the least treatable patients to public mental hospitals; doing this would tend to concentrate a treatment-oriented staff in the former and a custodially oriented staff in the latter. Instead, the centers and hospitals both need to be treatment oriented; there must be a choice between them for any given patient, based on differential diagnosis and differing clinical needs. A range of models for effecting liaison between the centers and public mental hospitals should be established.

Because of the disproportionately high incidence of unmet needs for medical care of physical illness in psychiatric patients, because of the greater acceptability of psychiatric care under a "medical" rather than a "mental" aegis, and because of the inseparability of various forms of mental and physical medicine in large numbers of patients, it is necessary to establish close working relationships with the medical community in general and specifically with comprehensive medical centers, where they exist. Various types of relationships between community mental health centers and comprehensive medical programs need to be tested; one of these relationships could be the integration of the former into the latter. The mental health centers should be encouraged to strengthen their ties to primary-care physicians and to psychiatrists in private practice far beyond what has evolved up to this time.

Since social service programs inevitably deal with psychosocial problems in the individuals and families they serve and since health care is inseparable from the other basic human needs of clients, community mental health centers should explore and establish effective patterns for close functional relationships with human service delivery centers. Again, one method of procedure may be an amalgamation of the two programs into an agency approach in comprehensive psychosocial care giving.

Consumers and the representatives of the consumers being served must both share in the decision-making processes governing the development of new organizations for the delivery of health care and in determining the priorities to be assigned to the services offered. In the case of community mental health centers this presupposes that these consumers and local representatives will be cognizant of the boundaries and capabilities of the mental health field. The principle of such participation marks a drastic departure from tradition and poses a host of new challenges to leaders. Nevertheless, if it is not accepted, the organization cannot succeed for lack of local confidence and support; this is particularly true of community mental health centers in inner city areas.

Substantial federal support is currently needed if the community mental health center movement is to survive. Funds should also be forthcoming from other public sectors of government—states, counties, and cities. In addition, fees from patients and third parties must continue to support a significant portion of direct treatment services, and there is some prospect, which should be encouraged, that in time they will also support some preventive and consultation services. Basically, however, new centers cannot now be established, nor can they offer a full



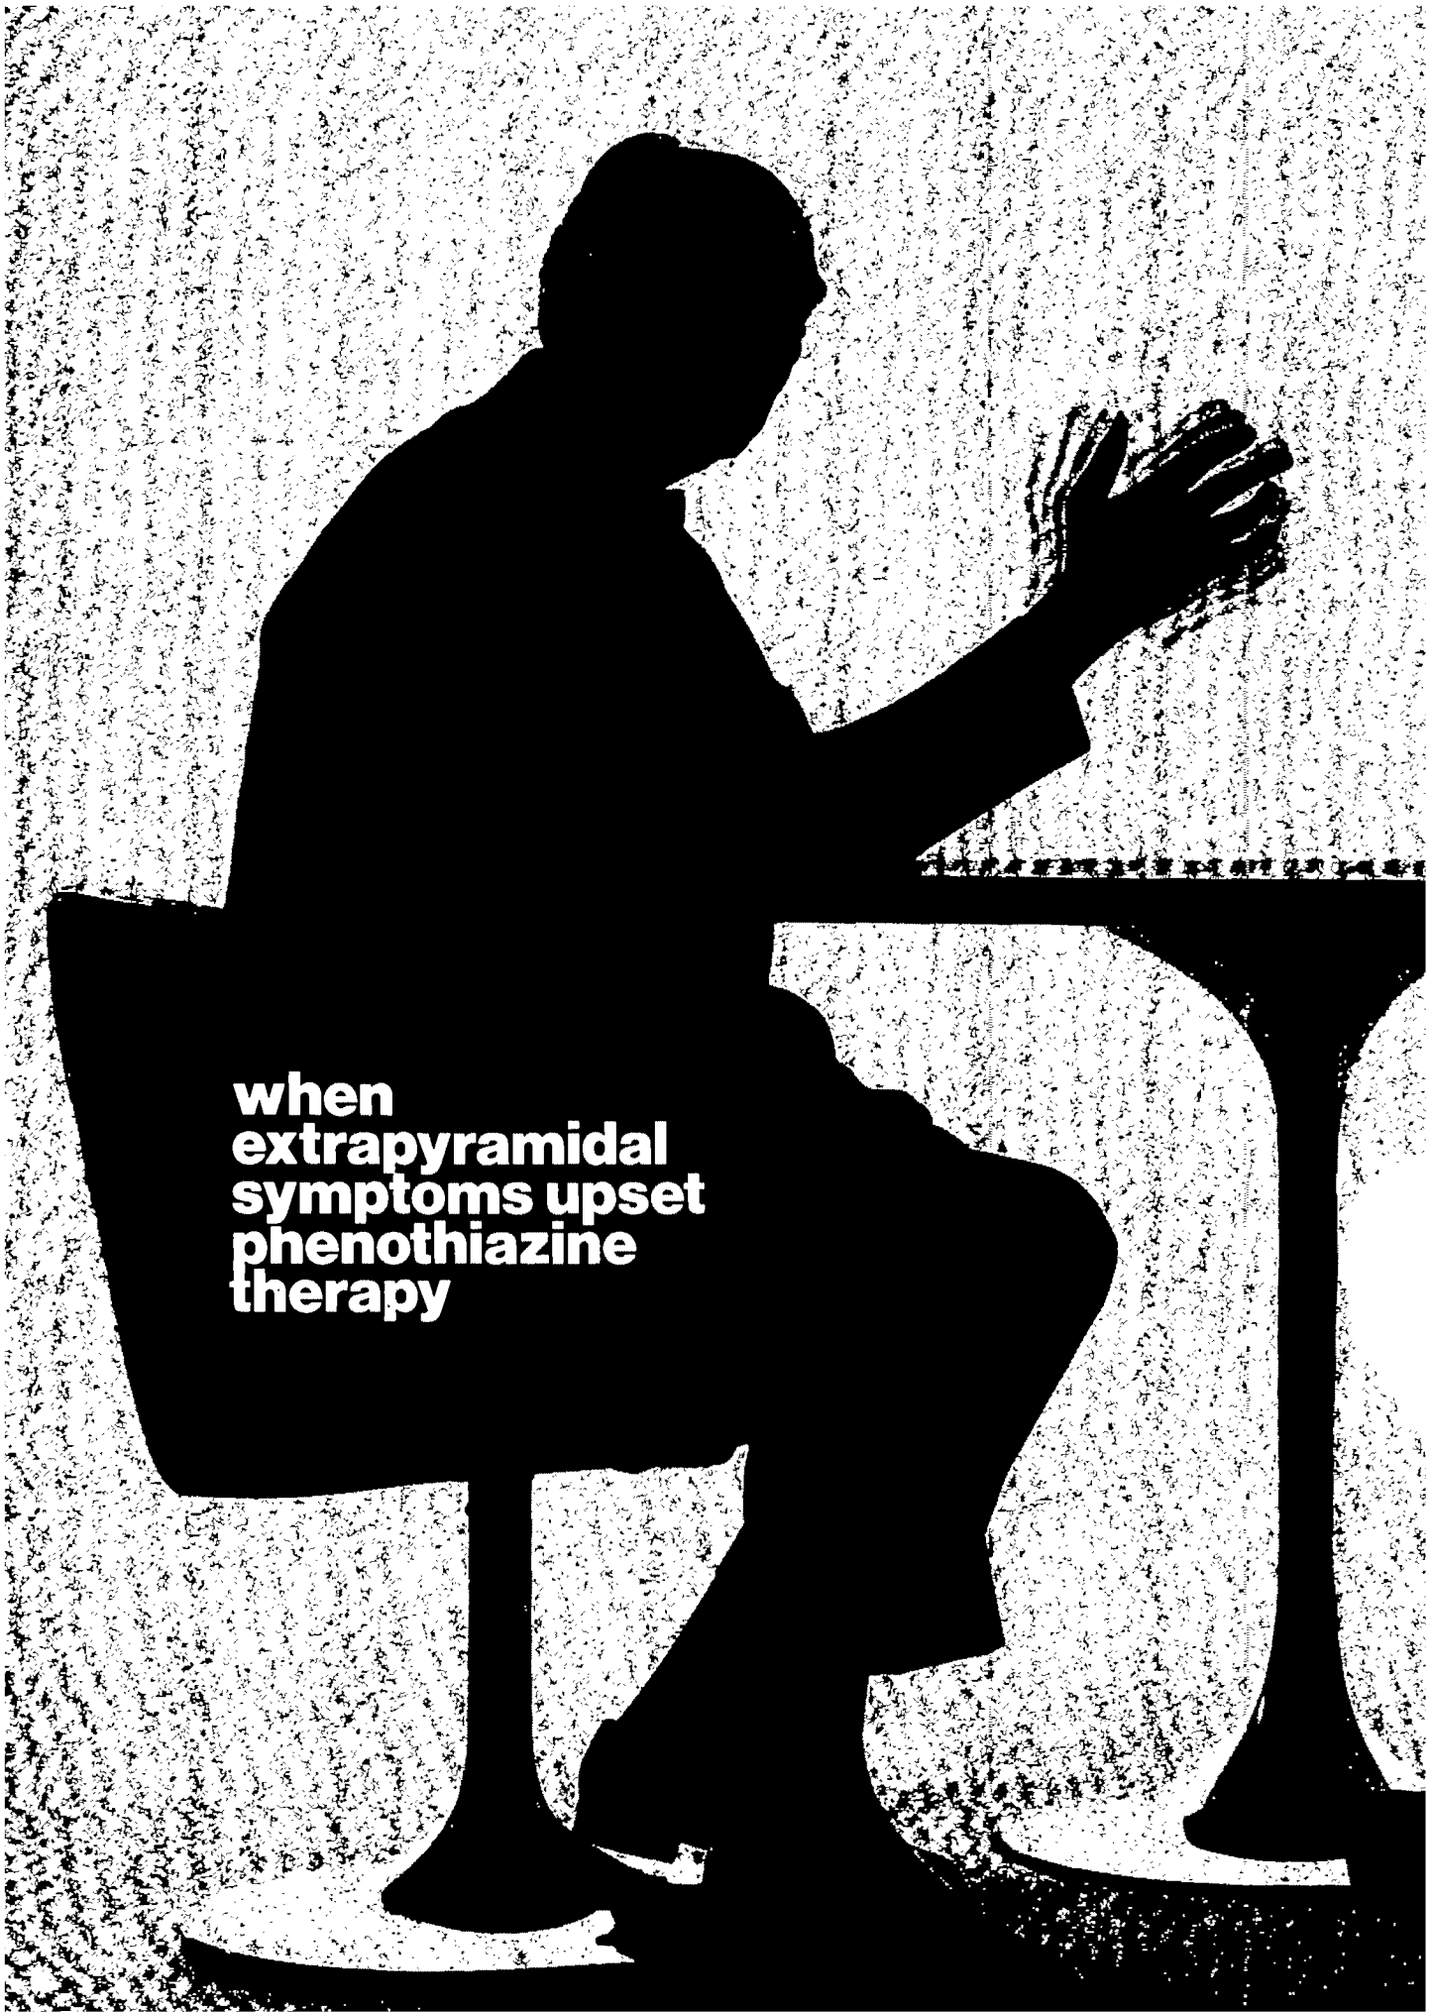
[1] The task force included: Israel Zwerling, M.D., chairman; Alan I. Levenson, M.D.; Lewis Kurke, M.D.; William G. Hollister, M.D.; and Robert H. Barnes, M.D.

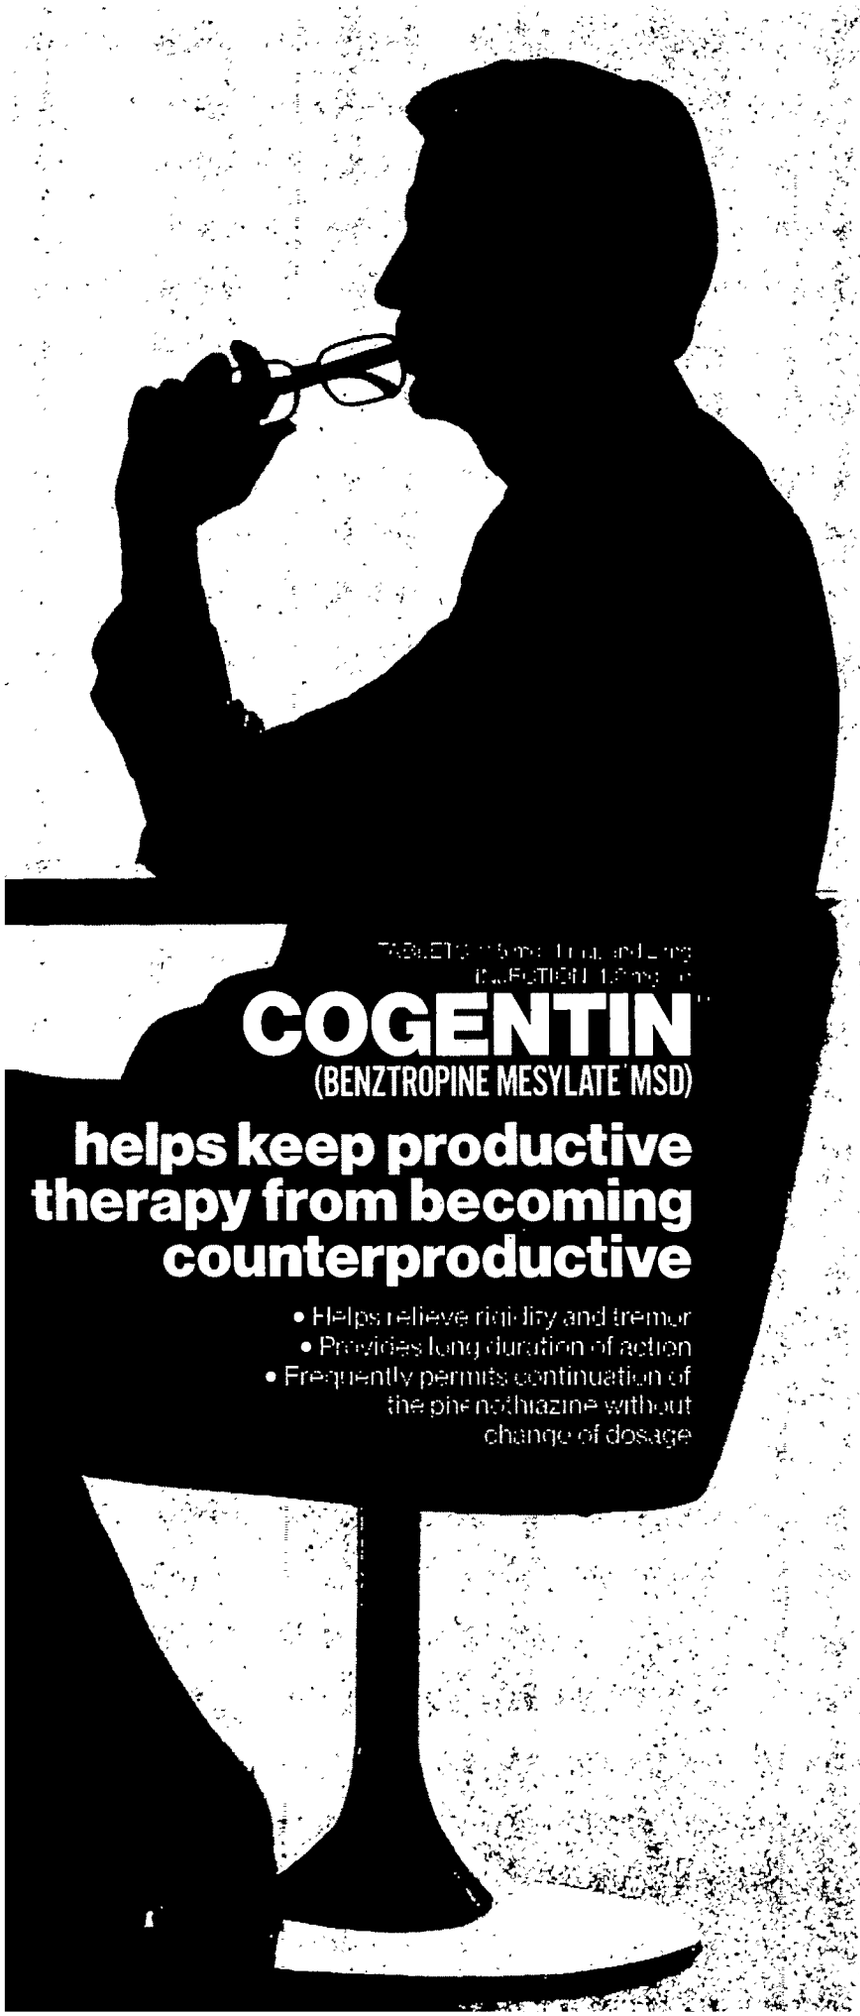
range of services, without federal support for construction, for staffing, and for training personnel.

The medical, including psychiatric, treatment program offered by a community mental health center must be the responsibility of a physician, preferably a psychiatrist, and should be directed by him. The center's total program, however, may be under the administrative direction of any health professional who has had adequate training in administration and experience in mental health services.

The inclusion of paraprofessional workers on the staffs of community mental health centers should be encouraged. These workers have facilitated communication and rapport between those who provide services and patients, their families, and the community. Through training and experience, many have successfully undertaken varied therapeutic roles in the centers. It is important, however, if high standards are to be achieved in the quality of care that is rendered, to avoid operating on the false principle that "anybody can do anything." The limits of the roles, responsibilities, and skills of professionals and paraprofessionals should be delineated. An effective in-service training program for paraprofessionals should be provided, as well as regular supervision by appropriate professional staff members.

Educational programs for psychiatrists, including residency and continuing education programs, should be immediately strengthened and rendered more relevant to the unfolding of community psychiatry and most particularly to the services that will be rendered by the community mental health centers.





AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally: **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

when
extrapyramidal
symptoms upset
phenothiazine
therapy

COGENTIN
(BENZTROPINE MESYLATE MSD)

helps keep productive therapy from becoming counterproductive

- Helps relieve rigidity and tremor
- Provides long duration of action
- Frequently permits continuation of the phenothiazine without change of dosage

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per cc, in 2-cc ampuls.

For more detailed information, consult your MSD representative or see the Direction Circular. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MSD MERCK SHARP & DOHME

APA SELF-ASSESSMENT PROGRAM

2nd Offering of the 1972 Program

The APA offers the self-assessment test to psychiatrists, residents, and other professionals as a means to stimulate self-learning. From the test results one evaluates his own strengths and weaknesses which enable him to pursue continuing education courses to strengthen his knowledge and skills.

Already there is a trend toward establishing continuing education credits as a requirement for relicensure and renewal of membership in medical organizations. The state of New Mexico requires it for relicensure; Oregon Medical Society requires it for continuing membership. Also, the APA is considering it as a future requirement for members to continue membership.

THE PROGRAM:

- Test items stress clinical competence and cover four broad subject areas: Patient Management Problems; Problems in Diagnosis; Problems in Treatment; Problems of Current Concern to Psychiatry.
- Each participant will receive a set of "norm tables" to enable him to see how he ranks among his peers in psychiatric knowledge and skills. These tables were developed from participants' scores in the first offering of the 1972 program.
- There are NO DEADLINES—Complete the test at your leisure and score your own exam with the answer key and bibliography provided.

TAKE ACTION NOW!

Complete the application form below and mail it with your check to APA—PKSAP-11, 1700 18th St. N.W., Washington, D.C. 20009.

APPLICATION FORM—DETACH AND RETURN

I wish to participate in the self-learning program and I am a: COST

☐ Psychiatric Resident-In-Training $15.00
( ) APA, Member-In-Training
( ) Non-member, Resident-In-Training
(Psychiatric residents in training who are not APA members must submit a letter from the program director [hospital administrator] certifying resident status)

☐ Member of the American Psychiatric Association (other than above) $25.00

☐ Physician (other than above) $40.00

☐ Mental Health Professional (other than above) $40.00

Make checks payable to APA—PKSAP-II. Send application form and check to the APA, 1700 18th St., N.W., Washington, D.C. 20009. Group applications are invited, however, *the individual names must accompany the request.* PLEASE ALLOW 3 to 4 WEEKS FOR DELIVERY.

PLEASE PRINT Name and Address to which the program packet is to be shipped:

Corrective Psychiatry and Journal of Social Therapy

Corrective Psychiatry and Journal of Social Therapy advances the social and cultural techniques of the therapeutic community. It fosters wider use of the scientific approach in institutional mental health fields. It disseminates information on the origin, nature, and treatment of anti-social behavior. It is a forum for progressive techniques and programs emphasizing practicability and functionally demonstrating the effectiveness of such programs.

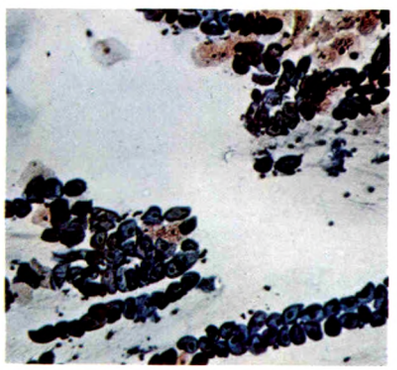
WHEN THE CAUSE OF EMOTIONAL DISTRESS IS LACK OF ESTROGEN... AS IN THE MENOPAUSE

In the patient near or over forty-five, many emotional complaints—including anxiety, depression, nervousness, fatigue and insomnia—are closely related to diminishing estrogen levels. The appearance of emotional symptoms often seems to correlate fairly well with declining estrogen levels.[1-4] These symptoms may occur even before physical changes become apparent.[1] And in patients where emotional instability has been latent, they may be unmasked and even magnified.[2]

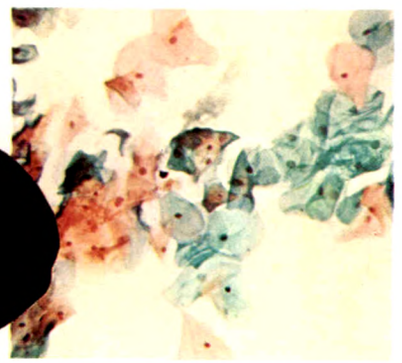
NO TRANQUILIZER CAN FILL THE VOID!

- Tranquilizers, at best, can provide only symptomatic relief of estrogen-related emotional symptoms of the menopause.
- Tranquilizers may obscure the physiologic need for estrogen replacement . . . delay needed therapy for estrogen-related tissue atrophy and bone degeneration.
- Some tranquilizers may produce paradoxical reactions which can complicate the clinical picture.
- Some tranquilizers may cause habituation with long term use.



By providing sound specific natural estrogen replacement, PREMARIN does what tranquilizers, sedatives, and antidepressants can't possibly do —relieves estrogen-related emotional symptoms of the menopause by treating the underlying deficiency.

At the same time, PREMARIN helps control physiologic symptoms of estrogen depletion, such as hot flushes, sweats, genital tissue atrophy, and, in selected cases, helps retard postmenopausal osteoporotic bone degeneration.†



Estrogen-related anxiety and depression usually respond to estrogen replacement therapy in a relatively short time.[3,5] Other "psychogenic" symptoms such as headaches, crying spells, insomnia, feelings of weakness and fatigue may also be relieved.[1,3,4,6] And in a large majority of patients, PREMARIN imparts a renewed sense of well-being.[7] PREMARIN. It gives patients back something they've lost. No tranquilizer can do that.

Whether your patient is a woman of forty-five suffering from estrogen-related emotional distress . . . or a grandmother of fifty-five with atrophic vaginitis . . . or a septuagenarian with osteoporosis and chronic back pain, she may often benefit from continued replacement therapy with PREMARIN.

PREMARIN is a natural estrogen. It contains natural estrogens exclusively—no synthetics. And PREMARIN provides the complete estrogen complex. Of all leading oral estrogens, it is the only one whose composition meets every specification for conjugated estrogens listed in the latest United States Pharmacopeia (Edition XVIII). PREMARIN. Thirty years of proven efficacy and patient acceptance. Virtually free from side effects. It's the most widely prescribed agent of its kind.

Patient, age 47, before therapy.* Vaginal cytogram shows virtual absence of superficial cells, indicating estrogen depletion: Superficial cells—5%/Intermediate cells—25%/Parabasal cells—70%.

Patient after PREMARIN therapy.* Vaginal cytogram shows reappearance of superficial cells, indicating improved estrogen status: Superficial cells—85%/Intermediate cells—15%/Parabasal cells—0%.

(Complete text of package circular.)

PREMARIN® (Conjugated Estrogens Tablets, U.S.P.)

Description: PREMARIN (Conjugated Estrogens, U.S.P.) is a mixture of estrogens, obtained exclusively from natural sources, occurring as the sodium salts of water-soluble estrogen sulfates blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17*α*-dihydroequilin, together with smaller amounts of 17*α*-estradiol, equilenin, and 17*α*-dihydroequilenin as salts of their sulfate esters.

Actions: Estrogens are responsible for development and maintenance of the female reproductive system and secondary sex characteristics. They cause the growth and development of the vagina, uterus, and fallopian tubes, and enlargement of the breasts. Indirectly, they contribute to the shaping of the skeleton, maintenance of tone and elasticity of urogenital structures, changes in the epiphyses of the long bones that allow for pubertal growth spurt and termination, growth of axillary and pubic hair, and pigmentation of the nipples and genitals. Estrogens are also involved in psychologic and emotional aspects of feminine behavior. As estrogen levels increase during the menstrual cycle, there is a sense of vigor and well-being, and in the menopausal period estrogens aid in relieving nervous symptoms (e.g. anxiety, depression and irritability) due to estrogen deficiency. Decline of estrogenic activity at the end of the menstrual cycle can bring on menstruation, although the cessation of progesterone secretion is the most important factor in the mature ovulatory cycle. However, in the pre- or non-ovulatory cycle, estrogen is the primary determinant in the onset of menstruation. Estrogens do not induce ovulation.

Estrogens affect calcium and phosphorus metabolism, and are involved in maintenance of normal bone structure. In prolonged estrogen deficiency states, administration of estrogen acts to prevent associated bone degenerative changes.

Estrogens appear to be responsible for the relatively greater amount of alpha-lipoprotein and correspondingly lower amount of beta-lipoprotein found in premenopausal women as compared with men.

Estrogens affect the release of pituitary gonadotropins and may also deplete the gonadotropic content of the pituitary.

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:

Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus; female hypogonadism; amenorrhea; and primary ovarian failure.

For abnormal uterine bleeding due to hormonal imbalance in the absence of organic pathology such as submucosal fibroids or uterine cancer.

For prevention of postpartum breast engorgement; also for inoperable progressing prostatic cancer (for palliation only when castration is not feasible or when castration failures or delayed escape following a response to castration have not occurred); breast cancer (for palliation only in women with progressing inoperable or roentgen resistant disease who are more than 5 years postmenopausal).

"Probably" effective: For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short-acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short-acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, re-examination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short-acting estrogen administration:

nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding (See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manifest

Dosage and Administration: PREMARIN (Conjugated Estrogens Tablets, U.S.P.) should be administered cyclically (3 weeks of daily estrogen and 1 week off) for all indications except selected cases of carcinoma and prevention of postpartum breast engorgement.

Menopausal Syndrome—1.25 mg. daily, cyclically. Adjust dosage upward or downward according to severity of symptoms and response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If breakthrough bleeding (bleeding or spotting during estrogen therapy) occurs, increase estrogen dosage as needed to stop bleeding. In the following cycle, employ the dosage level used to stop breakthrough bleeding in the previous cycle. In subsequent cycles, the estrogen dosage is gradually reduced to the lowest level which will maintain the patient symptom-free.

Postmenopause—as a protective measure against estrogen deficiency-induced degenerative changes (e.g. osteoporosis, atrophic vaginitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. daily and cyclically. Adjust dosage to lowest effective level.

Osteoporosis (to retard progression)—usual dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or without Pruritus—0.3 mg. to 1.25 mg. or more daily, depending upon the tissue response of the individual patient. Administer cyclically.

Abnormal Uterine Bleeding—(irregular, profuse, or prolonged uterine bleeding due to hormonal imbalance).

—*To stop bleeding*, 3.75 mg. to 7.5 mg. daily, in divided doses. Bleeding can usually be expected to stop within two to five days, but if it has not ceased within this time, an increase in dosage by 50 percent or more is recommended.

—*For Cycle 1*—The dosage required to stop bleeding is continued without interruption for 20 days. Otherwise, breakthrough bleeding will occur. During each of the last 5 to 10 days of estrogen therapy, give an oral progestin. Expect withdrawal bleeding in the next two to five days after cessation of therapy.

—*For Cycles 2, 3, 4*—3.75 mg. daily, in divided doses, for 20 days beginning on the fifth day of bleeding, and a progestin given during the last five days of estrogen therapy. Expect withdrawal bleeding in the next two to five days after cessation of therapy. Treatment is usually given during three or four cycles.

Hypogenitalism—In an attempt to bring about sexual and somatic maturation, 2.5 to 7.5 mg. daily, in divided doses for 20 days, followed by a rest period of 10 days' duration. If bleeding does not occur by the end of this period, the same dosage schedule is repeated. The number of courses of estrogen therapy necessary to produce bleeding may vary depending on the responsiveness of the endometrium.

If bleeding occurs before the end of the 10 day period, begin a 20 day estrogen-progestin cyclic regimen as in Amenorrhea.

Amenorrhea—In order to reproduce the hormone pattern of the ovary whereby there is bleeding from a progestational endometrium, begin a 20 day estrogen-progestin cyclic regimen with PREMARIN, 2.5 to 7.5 mg. daily in divided doses, for 20 days. During the last five days of estrogen therapy, give an oral progestin. If bleeding occurs before this regimen is concluded, therapy is discontinued and may be resumed on the fifth day of bleeding.

Mammary Carcinoma (for palliation in women with progressing inoperable or roentgen resistant disease who are more than 5 years postmenopausal)—Suggested dosage is 10 mg. three times daily for a period of at least three months.

Prostatic Carcinoma (for palliation when castration is not feasible or when castration failure or delayed escape have not occurred)—1.25 to 2.5 mg. three times daily. The effectiveness of therapy can be judged by phosphatase determinations as well as by symptomatic improvement of the patient.

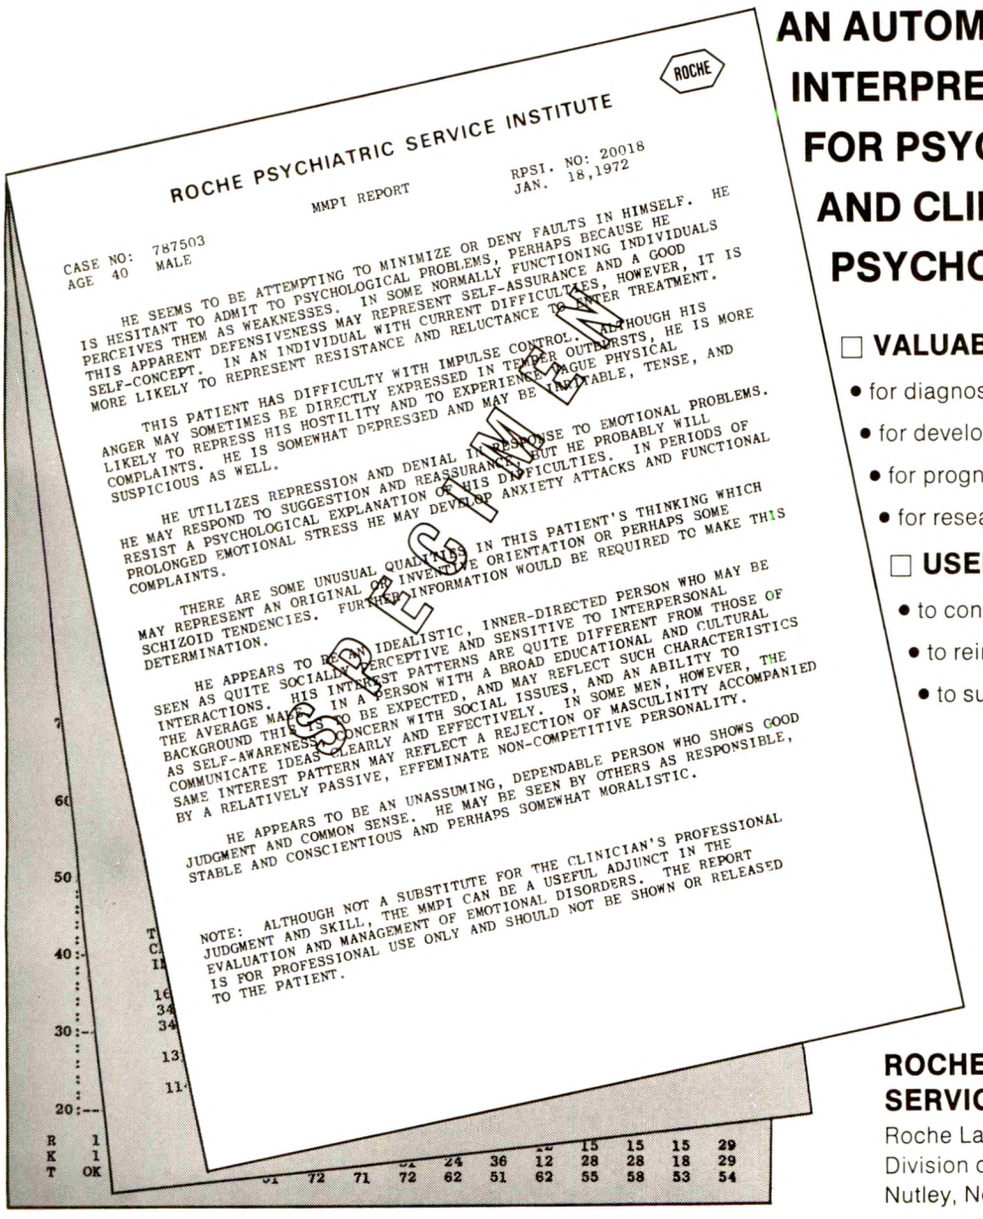
Prevention of Postpartum Breast Engorgement—3.75 mg. every four hours for five doses, or 1.25 mg. every four hours for five days.

How Supplied: PREMARIN (Conjugated Estrogens Tablets, U.S.P.)

No. 865—Each *purple* tablet contains 2.5 mg., in bottles of 100 and 1,000.

No. 866—Each *yellow* tablet contains 1.25 mg., in bottles of 100 and 1,000. Also in unit dose packages of 100.

No. 867—Each *red* tablet contains 0.625 mg., in bottles of 100 and 1,000.



No. 868—Each *green* tablet contains 0.3 mg., in bottles of 100 and 1,000.

THE PATIENT'S ANXIETY AND DEPRESSION NEED TREATMENT...

Her signs and symptoms suggested it — Your complete workup confirmed it.

noticed that palms were moist

said she lost interest in most things

thinks she has a "nervous stomach"

said she was tired and listless most of the time

Clinically significant anxiety may manifest itself by a variety of signs and symptoms, all of which are more readily apparent than those of depression. As a result, the coexisting depression that so frequently exists is often overlooked.

Many such patients are being treated with just a tranquilizer and nothing more. This can complicate or expose the underlying depression and even delay symptomatic improvement.

That's why an obviously anxious patient should be given a thorough evaluation with a complete history and physical examination.

If coexisting depression is affirmed, the physician should consider a medication specifically formulated to aid in treating the anxiety-depression syndrome.

TRIAVIL is that kind of agent.

Indicated for moderate to severe anxiety with depression, TRIAVIL is a dual component product consisting of perphenazine, a highly effective tranquilizer *and* amitriptyline HCl, an effective antidepressant. Working together, these two components treat *both* anxiety and depression, often relieving many of the somatic complaints so commonly associated with this disorder.

The drug may impair alertness and can potentiate the response to alcohol. Should not be used during the acute recovery phase following myocardial infarction. Should not be given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. Contraindicated in CNS depression and in bone marrow depression. Suicide is inherent in any depressive illness. Close supervision of patients is essential until satisfactory remission has taken place. This type of patient should not have easy access to large quantities of the drug.

TRIAVIL® 2-25: Each tablet contains 2 mg of perphenazine and 25 mg of amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains 2 mg of perphenazine and 10 mg of amitriptyline HCl.

TRIAVIL® 4-25: Each tablet contains 4 mg of perphenazine and 25 mg of amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains 4 mg of perphenazine and 10 mg of amitriptyline HCl.

INITIAL THERAPY
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

IN MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible. Elevation and lowering of blood-sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood-sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

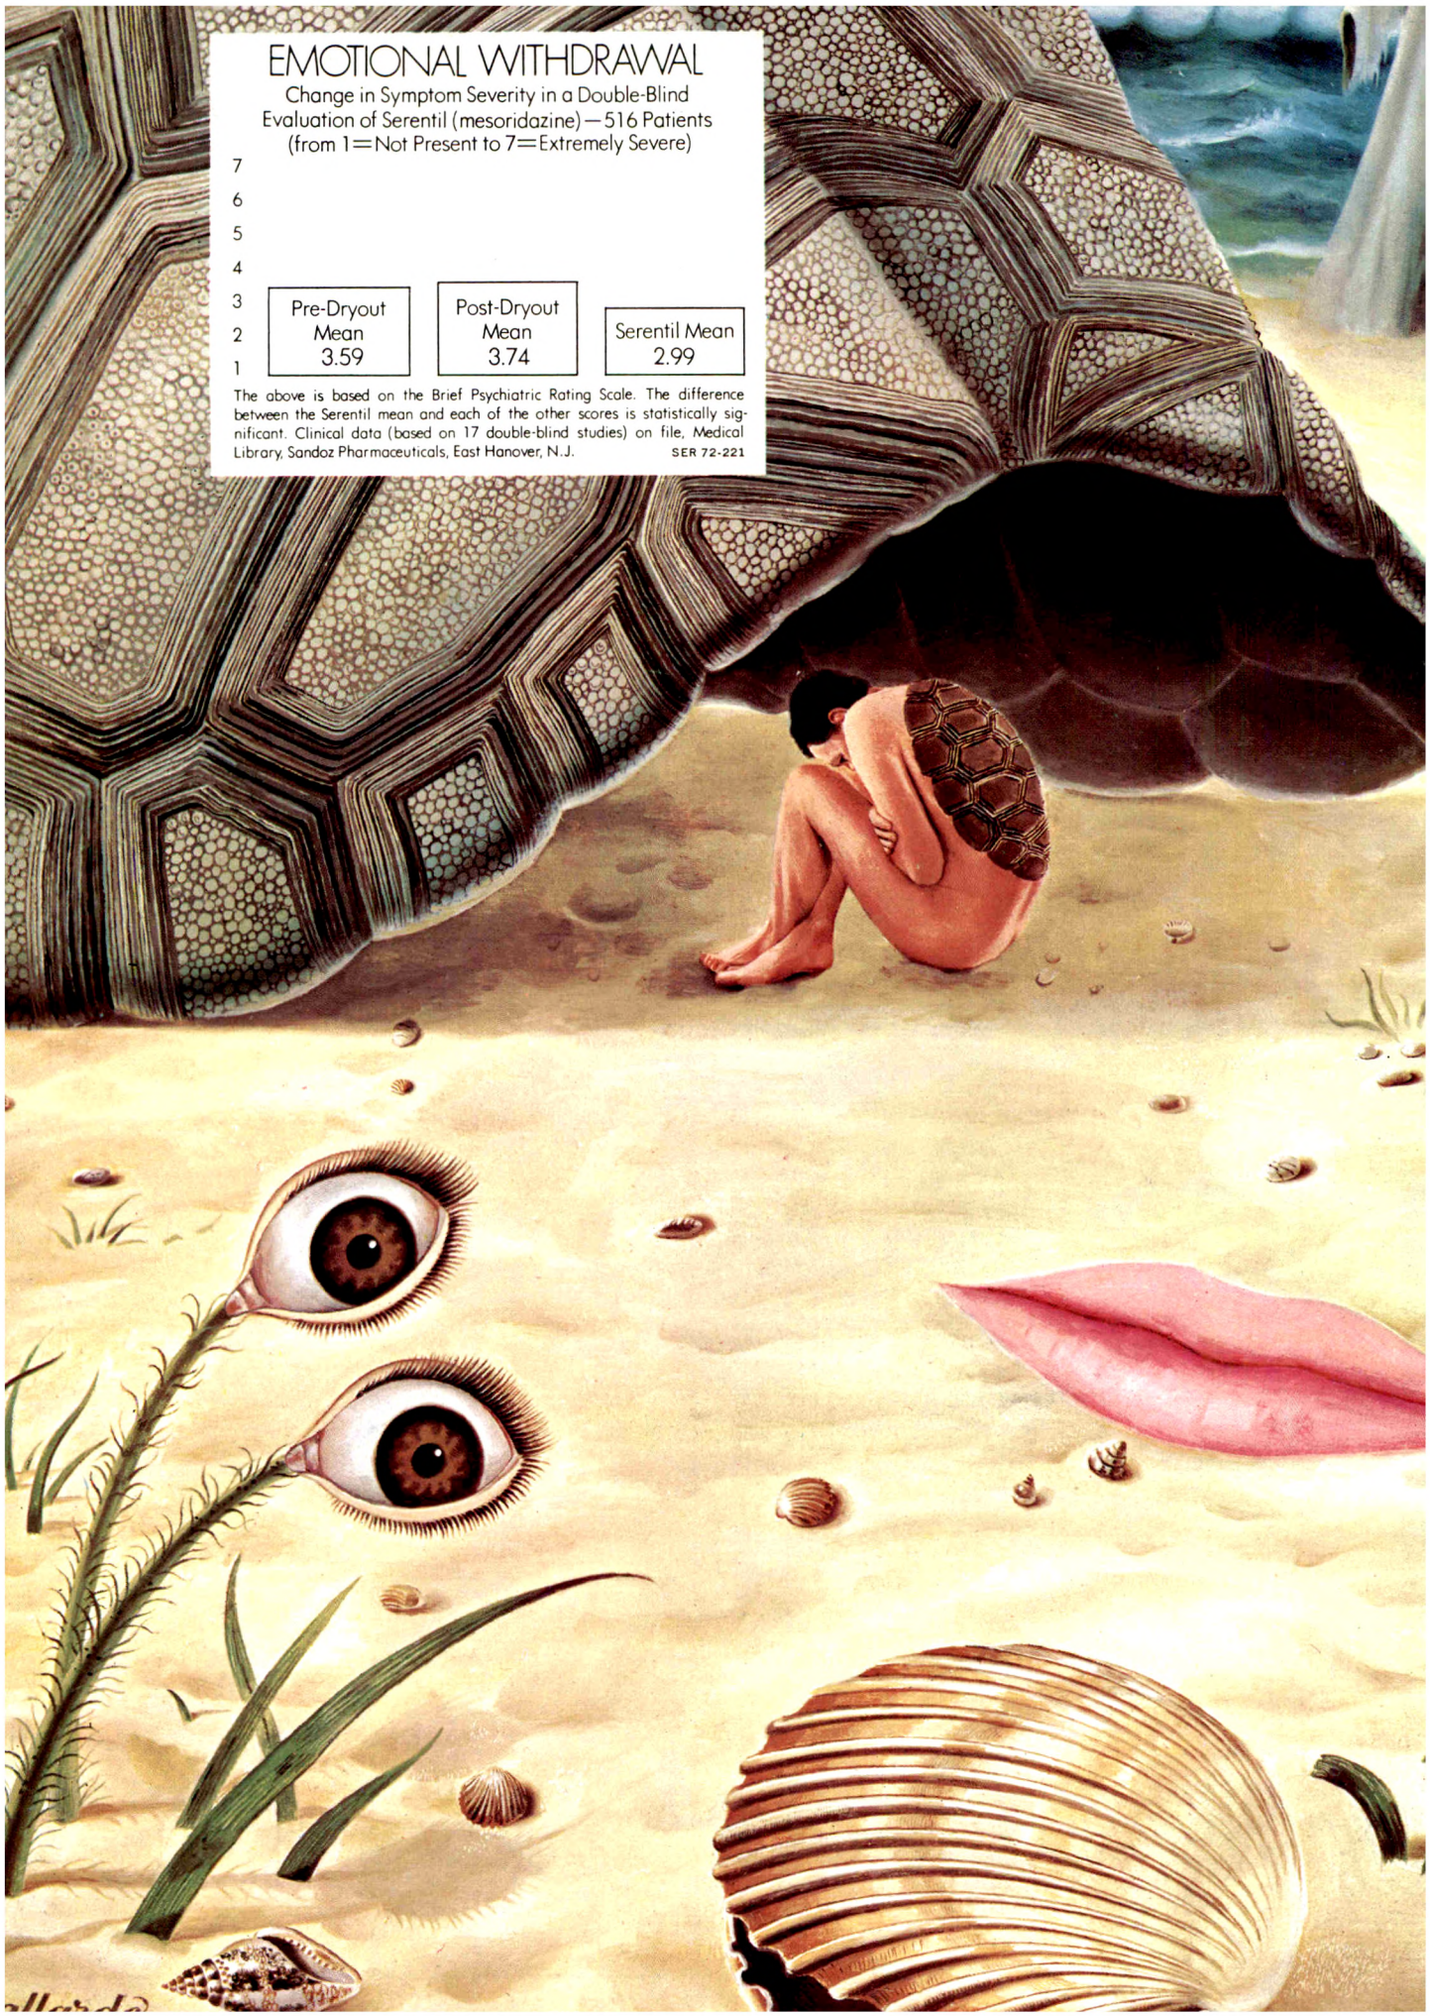
Contemporary Sexual Behavior
CRITICAL ISSUES IN THE 1970'S

Edited by JOSEPH ZUBIN & JOHN MONEY

More than twenty experts on the psychology, physiology, and biochemistry of sexual behavior —among them Masters and Johnson—present latest research in this burgeoning field. Among other questions, they consider the new feminism and women's sexuality, the use of drugs in treating sex offenders, and public attitudes toward sex education and pornography.



Based on the sixty-first annual meeting of the American Psychopathological Association $15.00

Money & Ehrhardt's
Man & Woman, Boy & Girl
DIFFERENTIATION AND DIMORPHISM OF GENDER IDENTITY FROM CONCEPTION TO MATURITY

In the first really comprehensive treatment of sexual differentiation, John Money and Anke Ehrhardt draw on the findings of psychology, genetics, embryology, endocrinology, and anthropology. Their multidisciplinary approach avoids the old arguments over nature versus nurture. What emerges is a new model of sexual differentiation that focuses instead on the *interaction* of heredity and environment.

SANDOZ

See next page for brief summary.

EMOTIONAL WITHDRAWAL
CONCEPTUAL DISORGANIZATION / ANXIETY
TENSION / HALLUCINATORY BEHAVIOR
SUSPICIOUSNESS / BLUNTED AFFECT

One or more of these symptoms in a schizophrenic is an indication for

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

Before prescribing, consult package circular.

HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST

AUTHORS: Louis S. Reed, Ph.D., Evelyn S. Myers, Patricia L. Scheidemandel

Those who hedge on granting the mentally ill adequate and equitable coverage under any national health insurance system have done so mainly on the ground that it would bankrupt the system. This book shows that this is not so. The most comprehensive study of the utilization and cost of care for mental disorders under health insurance ever undertaken, it gives facts and figures on more than 40 private health insurance plans or organizations, Medicare, other public programs in this country, and Canadian programs of hospital and medical service insurance. A wealth of data on inpatient care, in-hospital physicians' services, and ambulatory care is provided.

412 pages casebound $6.50
(2-6 copies, $6.00 ea.; 7-12 copies, $5.50 ea.; price for larger quantities supplied upon request)

EQUAL COVERAGE FOR THE MENTALLY ILL

The position statement of the American Psychiatric Association on the specifics of coverage of mental disorders under a National Health Insurance Program.

17 pages $1.00
(10-25 copies 10% discount; 26 or more copies 15% discount)

Here's what a group of anxious psychoneurotics (most with associated depressive symptoms) looked like after Valium® (diazepam) and psychotherapy

Pretreatment evaluations were compared with those of the second and fourth week of treatment, yielding a cumulative "improvement" score for each patient, symptom and observation interval.† A global assessment of the patient's emotional status was also made at each rating period.

Psychiatric Evaluation on a Modified BPRS*	Average scores of 17 patients—out of initial group of 21 patients—in study for 26 or more days**				
	Not present	Very mild/ mild	Mod- erate	Moder- ately severe/ severe	Extremely severe
1. Somatic concern	1	2	3	4	5
2. Anxiety	1	2	3	4	5
3. Emotional withdrawal	1	2	3	4	5
4. Guilt feelings	1	2	3	4	5
5. Tension	1	2	3	4	5
6. Depressive mood	1	2	3	4	5
7. Hostility	1	2	3	4	5
8. Motor retardation	1	2	3	4	5
9. Blunted affect	1	2	3	4	5

†With the exception of excessive anxiety and undue tension, the signs and symptoms shown in the Modified BPRS are not in themselves indications for Valium.

Valium® (diazepam) Tablets
Complete Prescribing Information:

Description: Valium (diazepam) is a benzodiazepine derivative developed through original Roche research. Chemically, diazepam is 7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one. It is a colorless, crystalline compound, insoluble in water and has a molecular weight of 284.74.

Pharmacology: In animals Valium (diazepam) appears to act on parts of the limbic system, the thalamus and hypothalamus, and induces calming effects. Valium (diazepam), unlike chlorpromazine and reserpine, has no demonstrable peripheral autonomic blocking action, nor does it produce extrapyramidal side effects; however, animals treated with Valium (diazepam) do have a transient ataxia at higher doses. Valium (diazepam) was found to have transient cardiovascular depressor effects in dogs. Long-term experiments in rats revealed no disturbances of endocrine function.

Oral LD_{50} of diazepam is 720 mg/kg in mice and 1240 mg/kg in rats. Intraperitoneal administration of 400 mg/kg to a monkey resulted in death on the sixth day.

Reproduction Studies: A series of rat reproduction studies was performed with diazepam in oral doses of 1, 10, 80 and 100 mg/kg. At 100 mg/kg there was a decrease in the number of pregnancies and surviving offspring in these rats. Neonatal survival of rats at doses lower than 100 mg/kg was within normal limits. Several neonates in these rat-reproduction studies showed skeletal or other defects. Further studies in rats at doses up to and including 80 mg/kg/day did not reveal teratological effects on the offspring.

In humans, measurable blood levels of Valium (diazepam) were obtained in maternal and cord blood, indicating placental transfer of the drug.

Indications: Valium (diazepam) is useful in the symptomatic relief of tension and anxiety states resulting from stressful circumstances or whenever somatic complaints are concomitants of emotional factors. It is useful in psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation.

In acute alcohol withdrawal, Valium (diazepam) may be useful in the symptomatic relief of acute agitation, tremor, impending or acute delirium tremens and hallucinosis.

Valium (diazepam) is a useful adjunct for the relief of skeletal muscle spasm due to reflex spasm to local pathology (such as inflammation of the muscles or joints, or secondary to trauma); spasticity caused by upper motor neuron disorders (such as cerebral palsy and paraplegia); athetosis; and stiff-man syndrome.

Oral Valium (diazepam) may be used adjunctively in convulsive disorders, although it has not proved useful as the sole therapy.

Contraindications: Valium (diazepam) is contraindicated in patients with a known hypersensitivity to this drug and, because of lack of sufficient clinical experience, in children under 6 months of age. It may be used in patients with open angle glaucoma who are receiving appropriate therapy, but it is contraindicated in acute narrow angle glaucoma.

Warnings: Valium (diazepam) is not of value in the treatment of psychotic patients and should not be employed in lieu of appropriate treatment. As is true of most preparations containing CNS-acting drugs, patients receiving Valium (diazepam) should be cautioned against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving a motor vehicle.

As with other agents which have anticonvulsant activity, when Valium (diazepam) is used as an adjunct in treating convulsive disorders, the possibility of an increase in the frequency and/or severity of grand mal seizures may require an increase in the dosage of standard anticonvulsant medication. Abrupt withdrawal of Valium (diazepam) in such cases may also be associated with a temporary increase in the frequency and/or severity of seizures.

Since Valium (diazepam) has a central nervous system depressant effect, patients should be advised against the simultaneous ingestion of alcohol and other CNS-depressant drugs during Valium (diazepam) therapy.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of diazepam (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). These were usually limited to those patients who had received excessive doses over an extended period of time. Particularly addiction-prone individuals (such as drug addicts or alcoholics) should be under careful surveillance when receiving diazepam or other psychotropic agents because of the predisposition

Use in Pregnancy: Use of any drug in pregnancy, lactation or in women of childbearing age requires that the potential benefit of the drug be weighed against its possible hazard to mother and child. (See *Reproduction Studies.*)

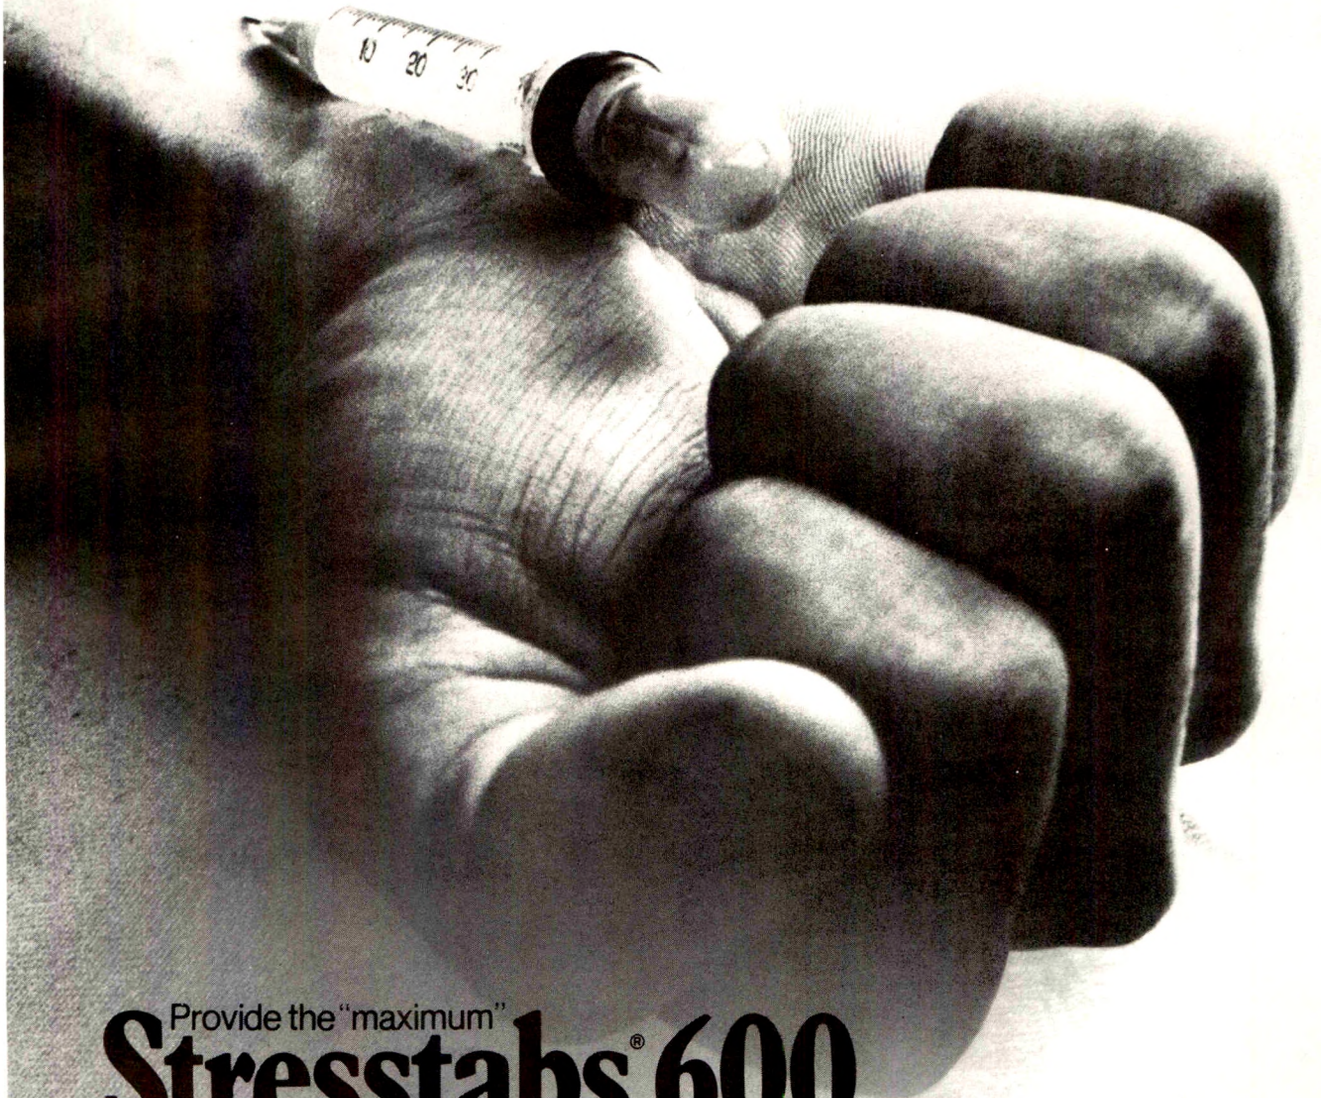
Management of Overdosage: Manifestations of Valium (diazepam) overdosage include somnolence, confusion, coma and diminished reflexes. Respiration, pulse and blood pressure should be monitored, as in all cases of drug overdosage, although, in general, these effects have been minimal following overdosage. General supportive measures should be employed, along with immediate gastric lavage. Intravenous fluids should be administered and an adequate airway maintained. Hypotension may be combated by the use of Levophed® (levarterenol) or Aramine (metaraminol). Ritalin (methylphenidate) or caffeine and sodium benzoate may be given to combat CNS-depressive effects. Dialysis is of limited value. As with the management of intentional overdosage with any drug, it should be borne in mind that multiple agents may have been ingested.

Precautions: If Valium (diazepam) is to be combined with other psychotropic agents or anticonvulsant drugs, careful consideration should be given to the pharmacology of the agents to be employed —particularly with known compounds which may potentiate the action of Valium (diazepam), such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The usual precautions are indicated for severely depressed patients or those in whom there is any evidence of latent depression; particularly the recognition that suicidal tendencies may be present and protective measures may be necessary. The usual precautions in treating patients with impaired renal or hepatic function should be observed.

In elderly and debilitated patients, it is recommended that the dosage be limited to the smallest effective amount to preclude the development of ataxia or oversedation (2 mg to 2½ mg once or twice daily, initially, to be increased gradually as needed and tolerated).

Adverse Reactions: Side effects most commonly reported were drowsiness, fatigue and ataxia. Infrequently encountered were confusion, constipation, depression, diplopia, dysarthria, headache, hypotension, incontinence, jaundice, changes in libido, nausea, changes in salivation, skin rash, slurred speech, tremor, urinary retention, vertigo and blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances and stimulation have been reported; should these occur, use of the drug should be discontinued.

Because of isolated reports of neutropenia and jaundice, periodic blood counts and liver function tests are advisable during long-term therapy. Minor changes in EEG patterns, usually low-voltage fast activity, have been observed in patients during and after Valium (diazepam) therapy and are of no known significance.



Dosage and Administration: Dosage should be individualized for maximum beneficial effect. While the usual daily dosages given below will meet the needs of most patients, there will be some who may require higher doses. In such cases dosage should be increased cautiously to avoid adverse effects.

Adults:	*USUAL DAILY DOSE*
Symptomatic Relief of Tension and Anxiety States and Psychoneurotic States.	Depending upon severity of symptoms—2 mg to 10 mg, 2 to 4 times daily
Symptomatic Relief in Acute Alcohol Withdrawal.	10 mg, 3 or 4 times during the first 24 hours, reducing to 5 mg, 3 or 4 times daily as needed
Adjunctively for Relief of Skeletal Muscle Spasm.	2 mg to 10 mg, 3 or 4 times daily
Adjunctively in Convulsive Disorders.	2 mg to 10 mg, 2 to 4 times daily
Geriatric Patients, or in the presence of debilitating disease.	2 mg to 2½ mg, 1 or 2 times daily initially; increase gradually as needed and tolerated
Children:	
Because of varied responses to CNS-acting drugs, initiate therapy with lowest dose and increase as required. Not for use in children under 6 months.	1 mg to 2½ mg, 3 or 4 times daily initially; increase gradually as needed and tolerated

How Supplied: For oral administration: Valium (diazepam) scored tablets—2 mg, white; 5 mg, yellow; and 10 mg, blue—bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Lederle LEDERLE LABORATORIES, Division of American Cyanamid Company, Pearl River, New York 10965 732-3

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa. 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)
TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.
Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

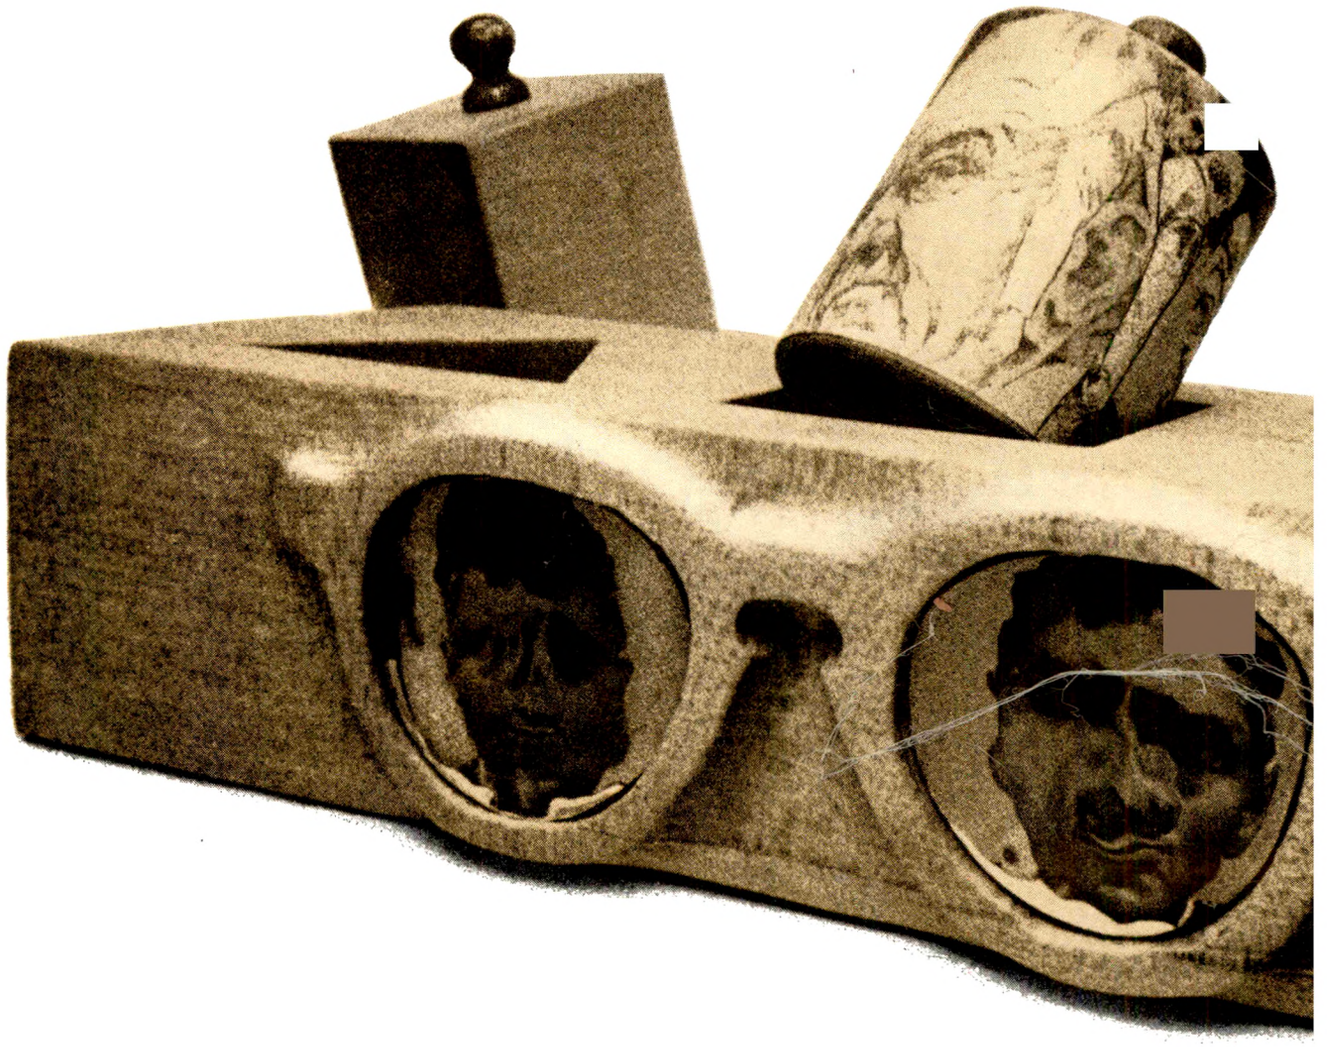
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening.
Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate.
The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.



HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.
Consult complete product literature before prescribing.

CIBA Pharmaceutical Company
Division of CIBA-GEIGY Corporation
Summit, New Jersey 07901 2/4753 17

*This drug has been evaluated as possibly effective for this indication. See brief prescribing information.

CIBA

Help improve your depressed patients' ability to cope.

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.

Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug, response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50. 250 and 1000 tablets.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

For graduate student
John R., lying down
to sleep was a real
eye-opener.
11
12
1

Meet John R., age 33.
B.A., *cum laude*
Ph.D. in the making.

But until recently, it looked as if he might not make it. His problem: insomnia. Clinically confirmed. Unwanted wakefulness every night. It was wreaking havoc with his studies. And with his personal relationships, too.

Quāālude®-300 (methaqualone) helped solve John R.'s problem...but under rather unusual circumstances.

John R. volunteered to participate...along with nine other confirmed insomniacs...in a sleep study[1] of experimental design, single blind, to evaluate Quāālude-300 against a placebo. Sequentially, there were three placebo nights, followed by three drug nights, followed by four placebo nights. EEG recordings were obtained continuously from 2300 to 0600 hours. He returned for a second period of 10 days three weeks later.

Goldstein, *et al.*,[2] reported that two statistically significant benefits of Quāālude-300 were apparent in this particular study.

- Time needed for the insomniacs to fall asleep *was reduced.*
- Intermittent periods of wakefulness...so common among insomniacs...*were shorter* when Quāālude was used.

Other clinical studies, plus experience in medical practice throughout the world, have established the therapeutic value of non-barbiturate methaqualone: Quāālude can induce sleep in 10 to 30 minutes; it usually helps produce 6 to 8 hours of restful sleep; Quāālude patients usually awaken easily and without evidence of "hangover."

Side effects reported have been mild, transient, and have often proved to be statistically insignificant when compared to placebo effects. Psychological dependence occasionally occurs, physical dependence rarely reported. (See Brief Summary of Prescribing Information.)

Maybe your patients can benefit as John R. did, by your prescribing Quāālude.

Brief Summary of Prescribing Information

Indications: Sleep. Daytime sedation.

Usual Adult Dose: *For sleep,* 150-300 mg. at bedtime. For patients previously on other hypnotics, 300 mg. for five to seven nights. *For sedation,* 75 mg. t.i.d. or q.i.d. Not recommended in children. Dosage should be individualized for aged, debilitated or highly agitated patients.

Overdosage: Acute overdosage may result in delirium and coma, with restlessness and hypertonia, progressing to convulsions. Evacuate gastric contents, maintain adequate ventilation and support blood pressure, if necessary. Dialysis may be helpful. Analeptics are contraindicated. Succinylcholine accompanied by assisted respiration has been proposed for prolonged convulsions. Overdoses of methaqualone appear to be less often associated with cardiac or respiratory depression than are overdoses of oral barbiturates, but shock and respiratory arrest may occasionally occur.

Contraindications: Contraindicated in women who are or may become pregnant; or patients with known hypersensitivity.

Warnings: Take hypnotic dose only at bedtime. Not recommended in children. Warn patient on Quāālude® (methaqualone) against driving a car or operating dangerous machinery. Care needed when administered with other sedatives, analgesic or psychotropic drugs or alcohol because of possible additive effects. Pending longer clinical experience, Quāālude should not be used continuously for periods exceeding three months. *Psychological dependence* occasionally occurs. *Physical dependence* rarely reported. However, caution needed with addiction-prone patients.

Precautions: Use with caution and prescribe small quantities in patients with anxiety states where impending depression or suicidal tendencies exist. Give in reduced doses, if at all, in patients with impaired hepatic function.

Adverse Reactions: *Neuropsychiatric:* headache, hangover, fatigue, dizziness, torpor, transient paresthesia of the extremities. An occasional patient has experienced restlessness or anxiety. *Hematologic:* aplastic anemia possibly related to methaqualone has been very rarely reported. *Gastrointestinal:* dry mouth, anorexia, nausea, emesis, epigastric discomfort, diarrhea. *Dermatologic:* diaphoresis, bromhidrosis, exanthema. Urticaria has been particularly well documented.

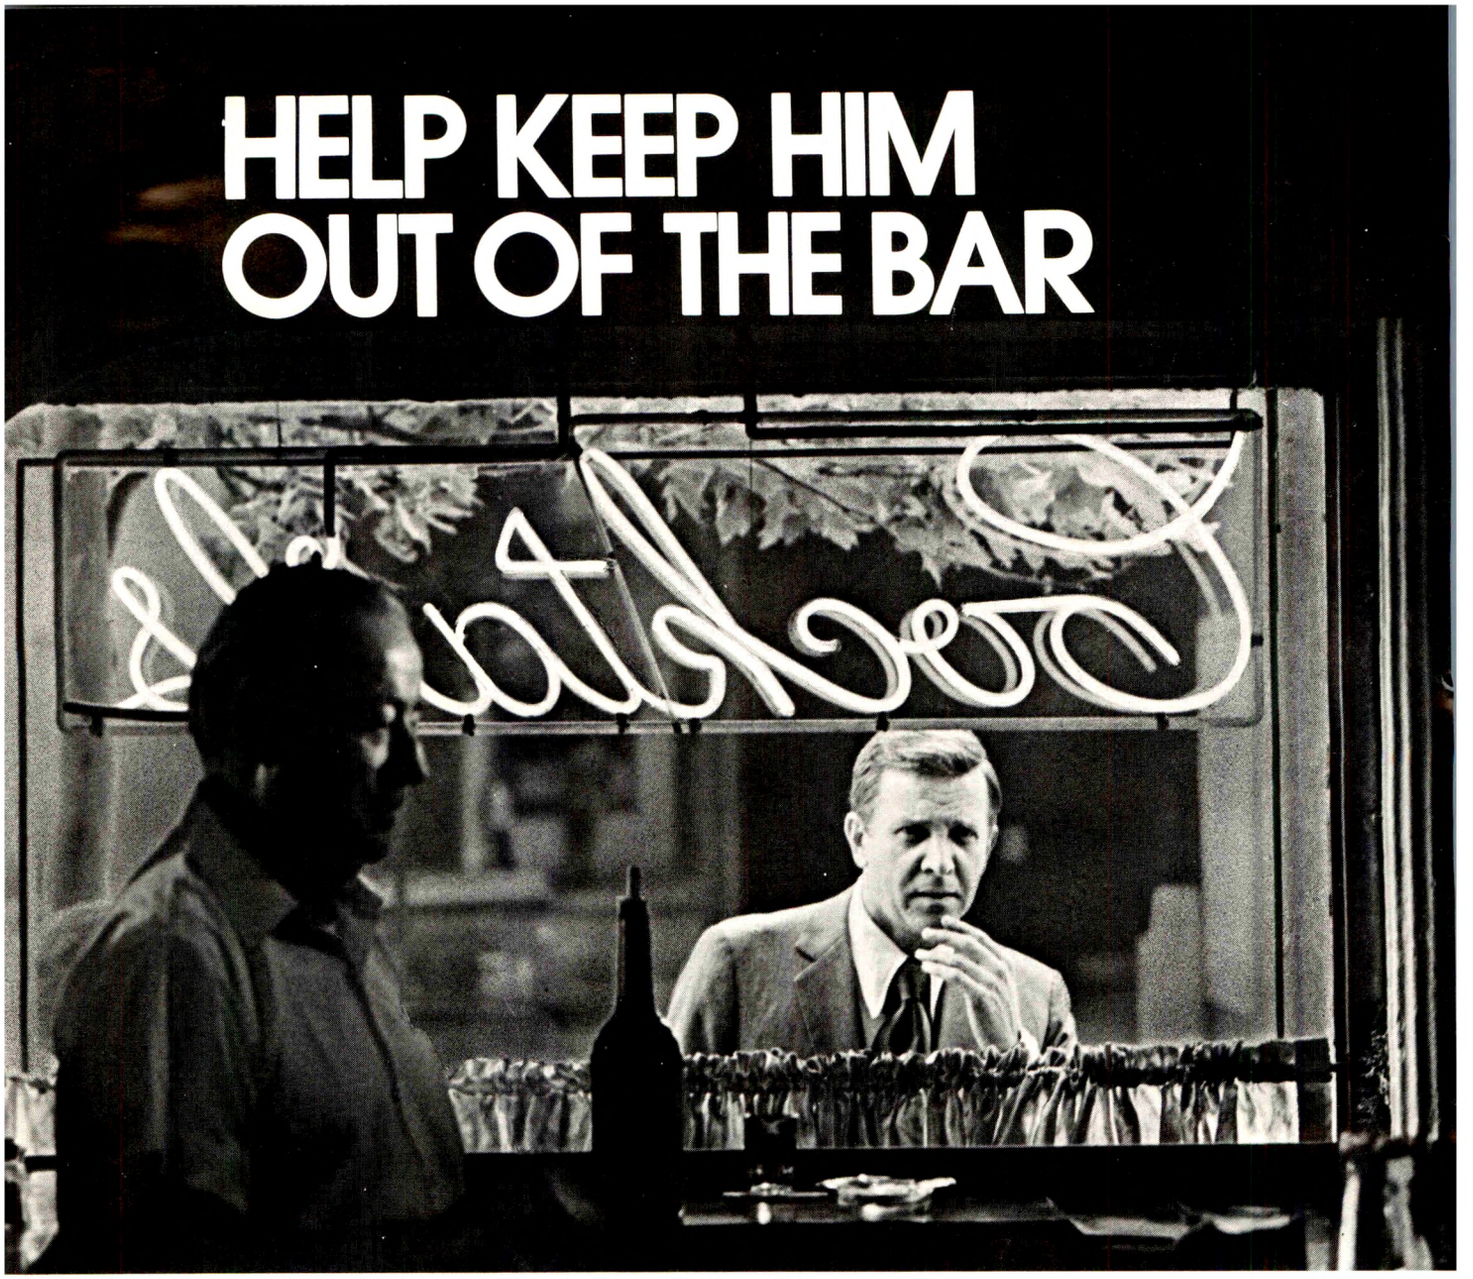
Supplied: Quāālude-150 (150 mg. white, scored tablets). Quāālude-300 (300 mg. white, scored tablets).

Consult complete literature before prescribing.

1. A Comparative Study of the Effects of Methaqualone...on Sleep in Male Chronic Insomniacs, Goldstein, L. *et al.: J. Clin. Pharmacol. 10:* 258-268, 1970.
2. An Analysis of Effects of Methaqualone...on Sleep in Insomniac Subjects, Goldstein, L. *et al.: Res. Communications in Chem. Path. and Pharmacol. 2:* 927-933, 1971.

a non-barbiturate

Quāālude®-300



(methaqualone) 300 mg. tablets

For a good morning after a sleep-through night.

WILLIAM H. RORER, INC.
Fort Washington, Pa. 19034

RORER

HELP KEEP HIM OUT OF THE BAR

Bars may draw him like a magnet. Not for social reasons as much as antisocial ones. His drinking hurts himself and others close to him. He's an alcoholic, a public health problem, and a menace behind the wheel of a car. He's ill and needs your help and treatment.

For more than 20 years now, ANTABUSE has proved its effectiveness as a medical adjunct in the management of alcoholics who want to recover. ANTABUSE offers strong deterrent action. It can help keep the alcoholic sober so that he can participate in a total treatment program utilizing many supportive measures.

Once the alcoholic accepts ANTABUSE therapy, he has made his decision to stop drinking. By taking his tablet each day, he daily strengthens his resolve. The patient must be given a clear and detailed description of the effects of ingesting alcohol after he has taken ANTABUSE even up to 14 days after the last dose. ANTABUSE is nonhabituating; there is no danger of cross-addiction.

ANTABUSE®

Brand of DISULFIRAM

a strong deterrent for the alcoholic who doesn't want to drink

See opposite page for brief summary of prescribing information.

ANTABUSE® (DISULFIRAM)

a strong deterrent for the alcoholic who doesn't want to drink

BRIEF SUMMARY *(For full prescribing information, see package circular.)*

ANTABUSE® Brand of disulfiram
In Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS

ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hapatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, it should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokaliemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

Ayerst. AYERST LABORATORIES
New York, N.Y. 10017

7306

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride ℂ
(methylphenidate hydrochloride)
TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

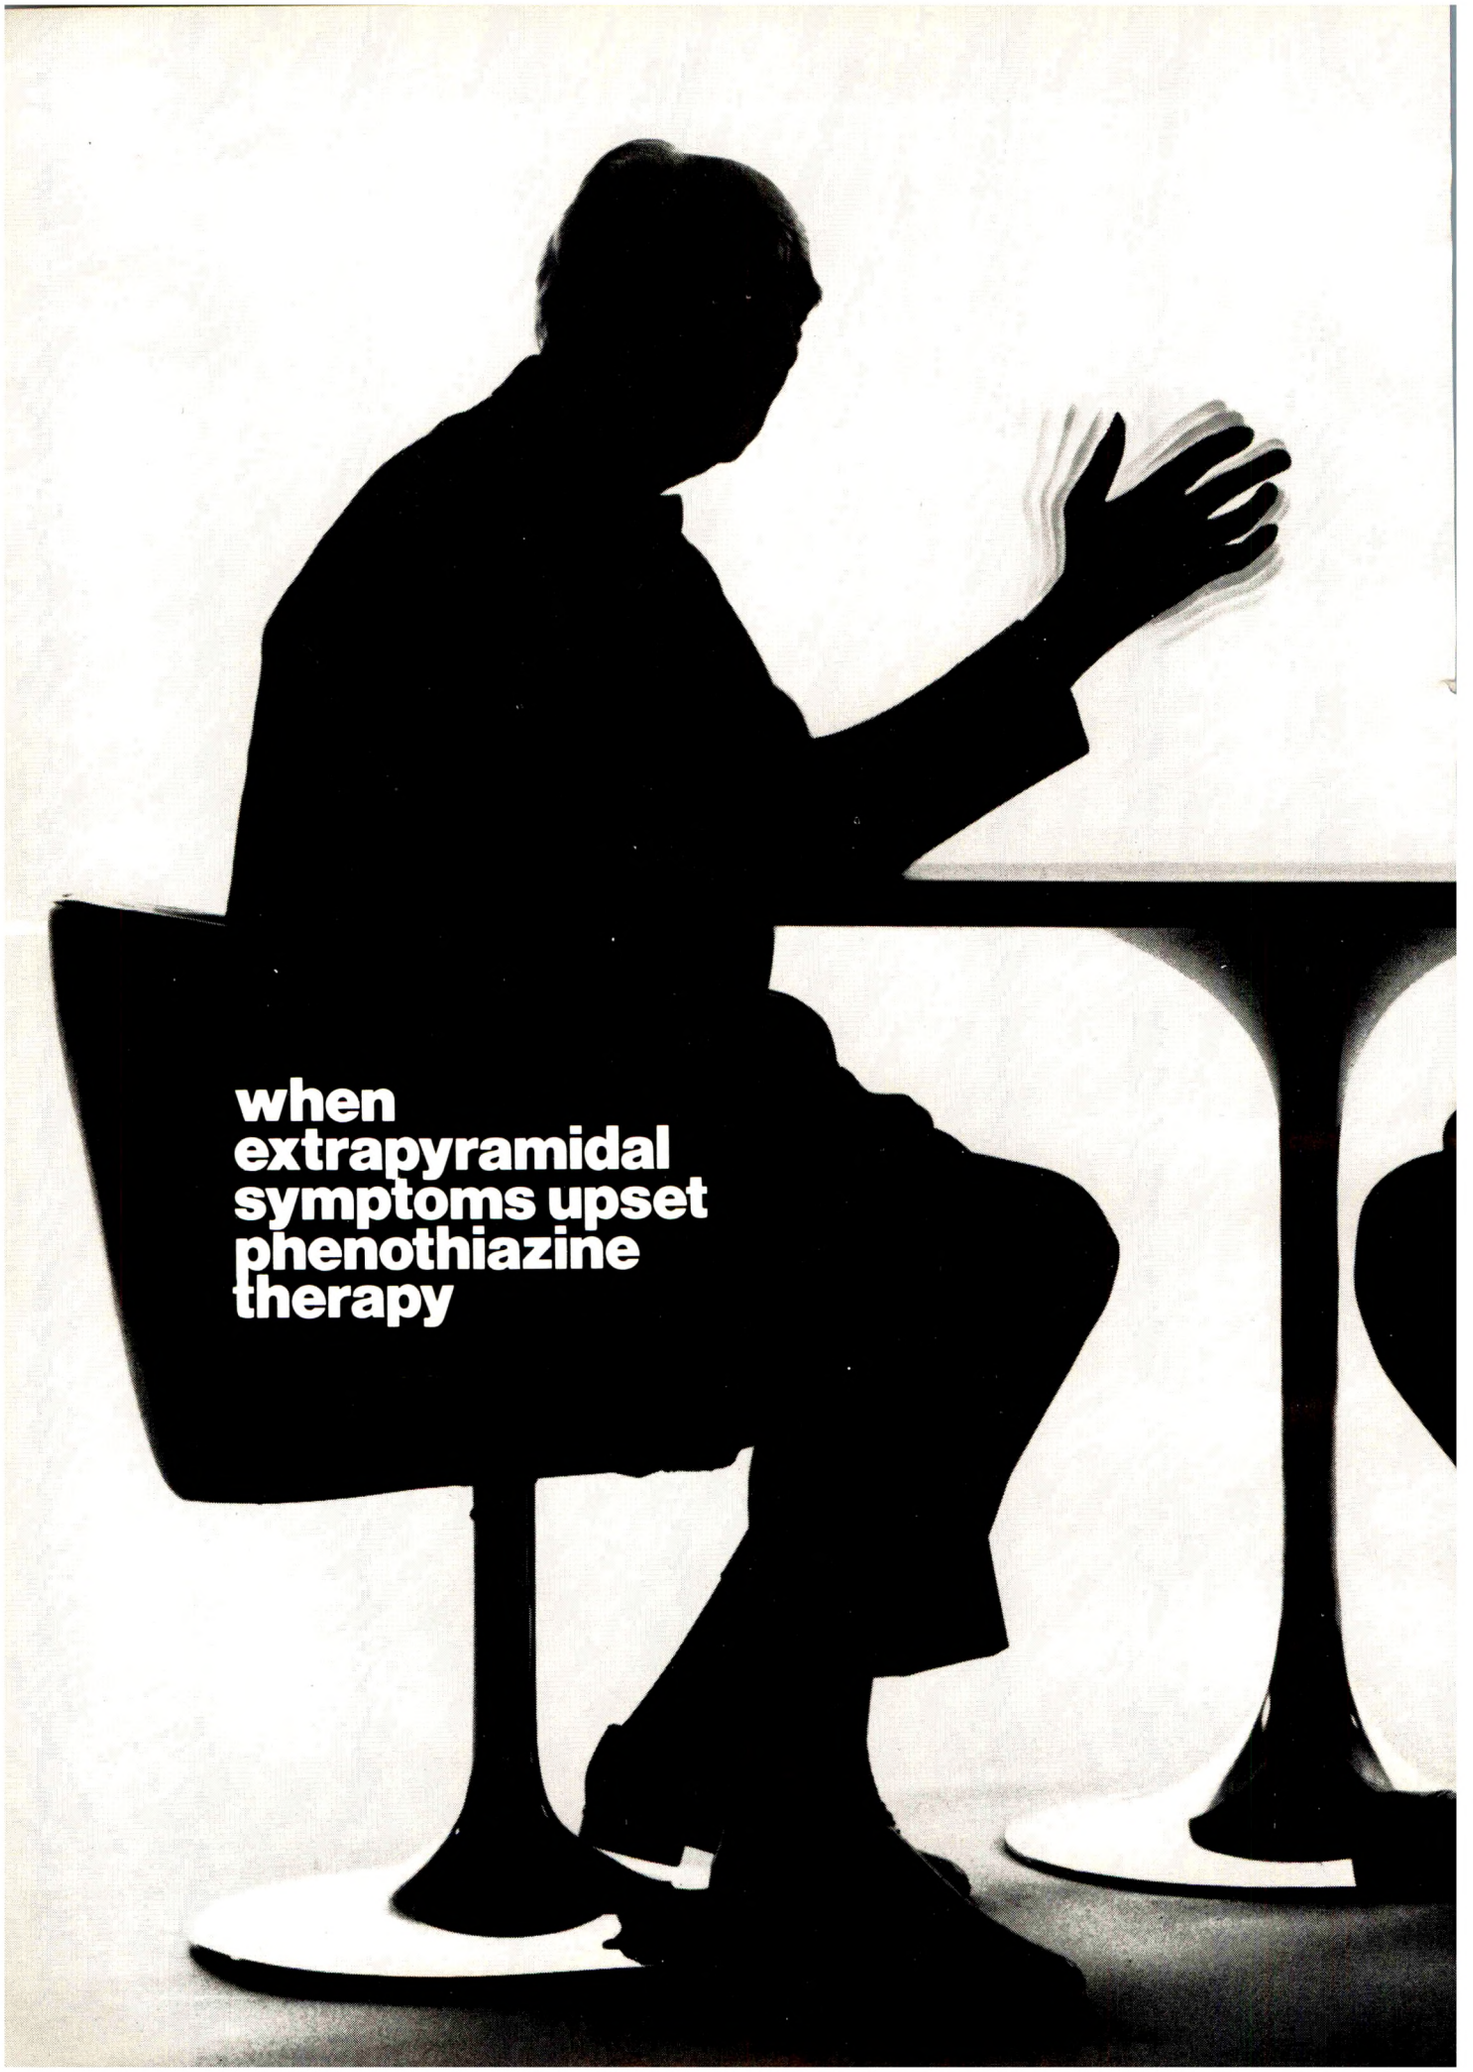
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

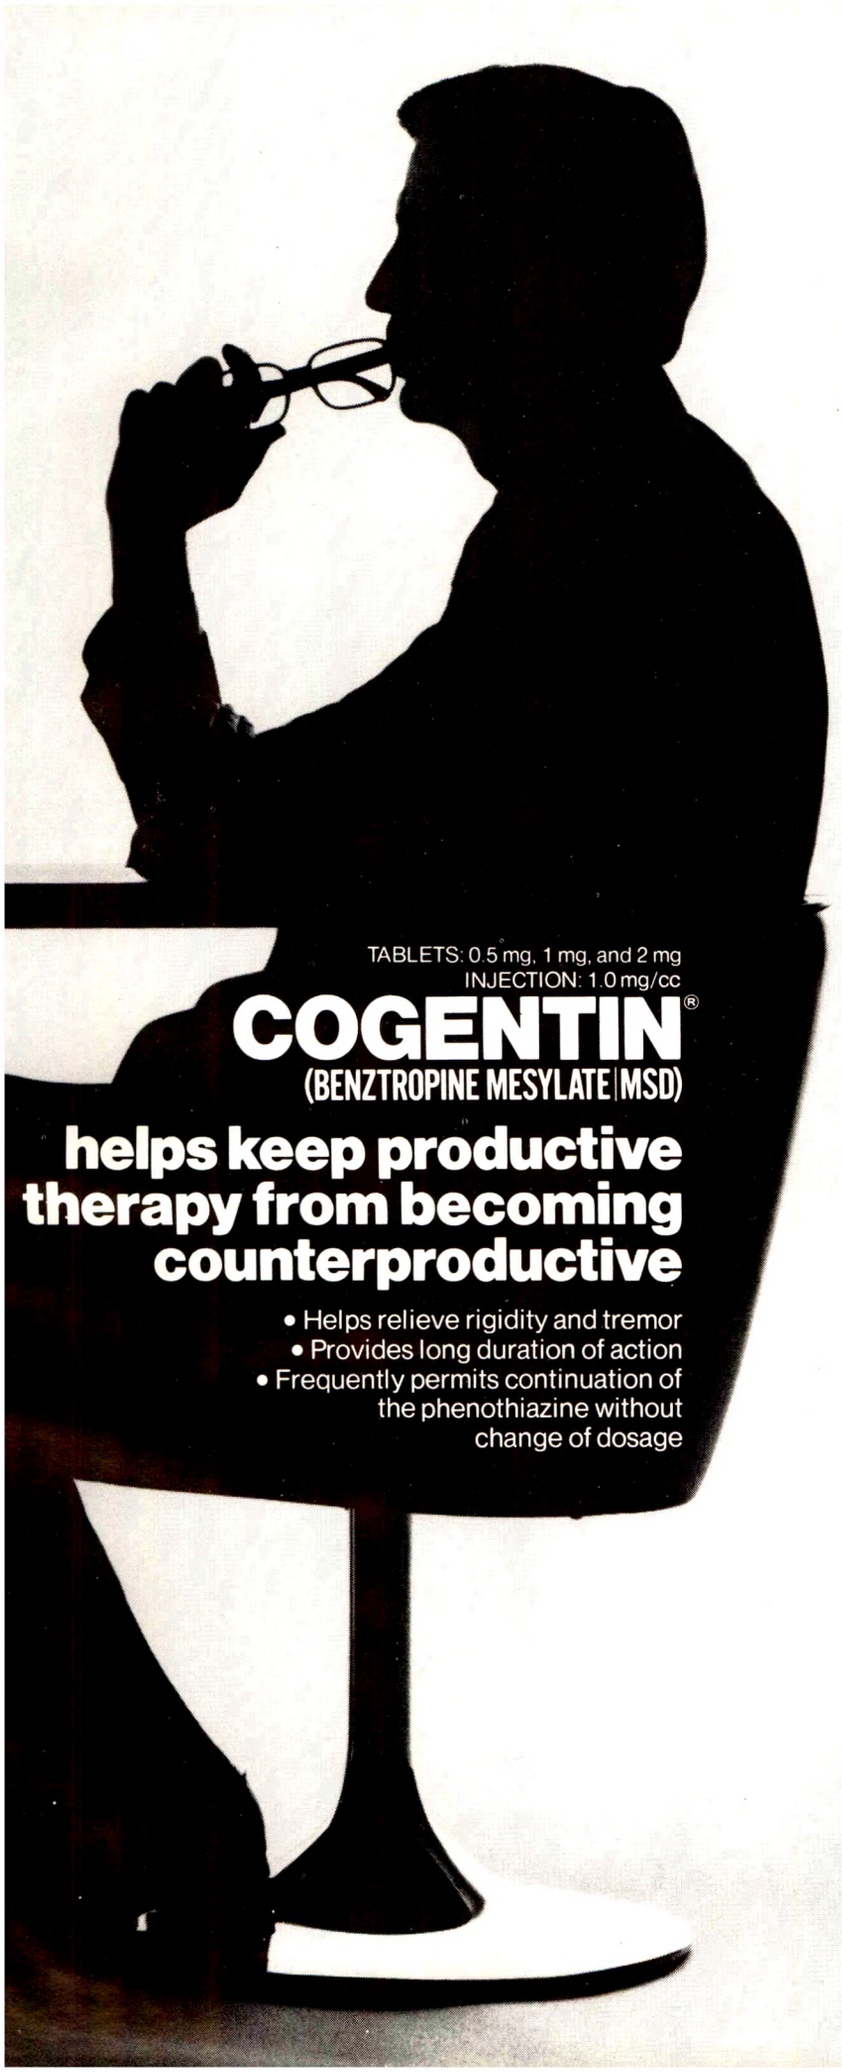
Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening.
Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.



DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.



HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.
Consult complete product literature before prescribing.

*This drug has been evaluated as possibly effective for this indication. See brief prescribing information.

CIBA

when
extrapyramidal
symptoms upset
phenothiazine
therapy

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/cc

COGENTIN®
(BENZTROPINE MESYLATE | MSD)

helps keep productive therapy from becoming counterproductive

- Helps relieve rigidity and tremor
- Provides long duration of action
- Frequently permits continuation of the phenothiazine without change of dosage

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.
Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.
May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.
Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) If they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per cc, in 2-cc ampuls.

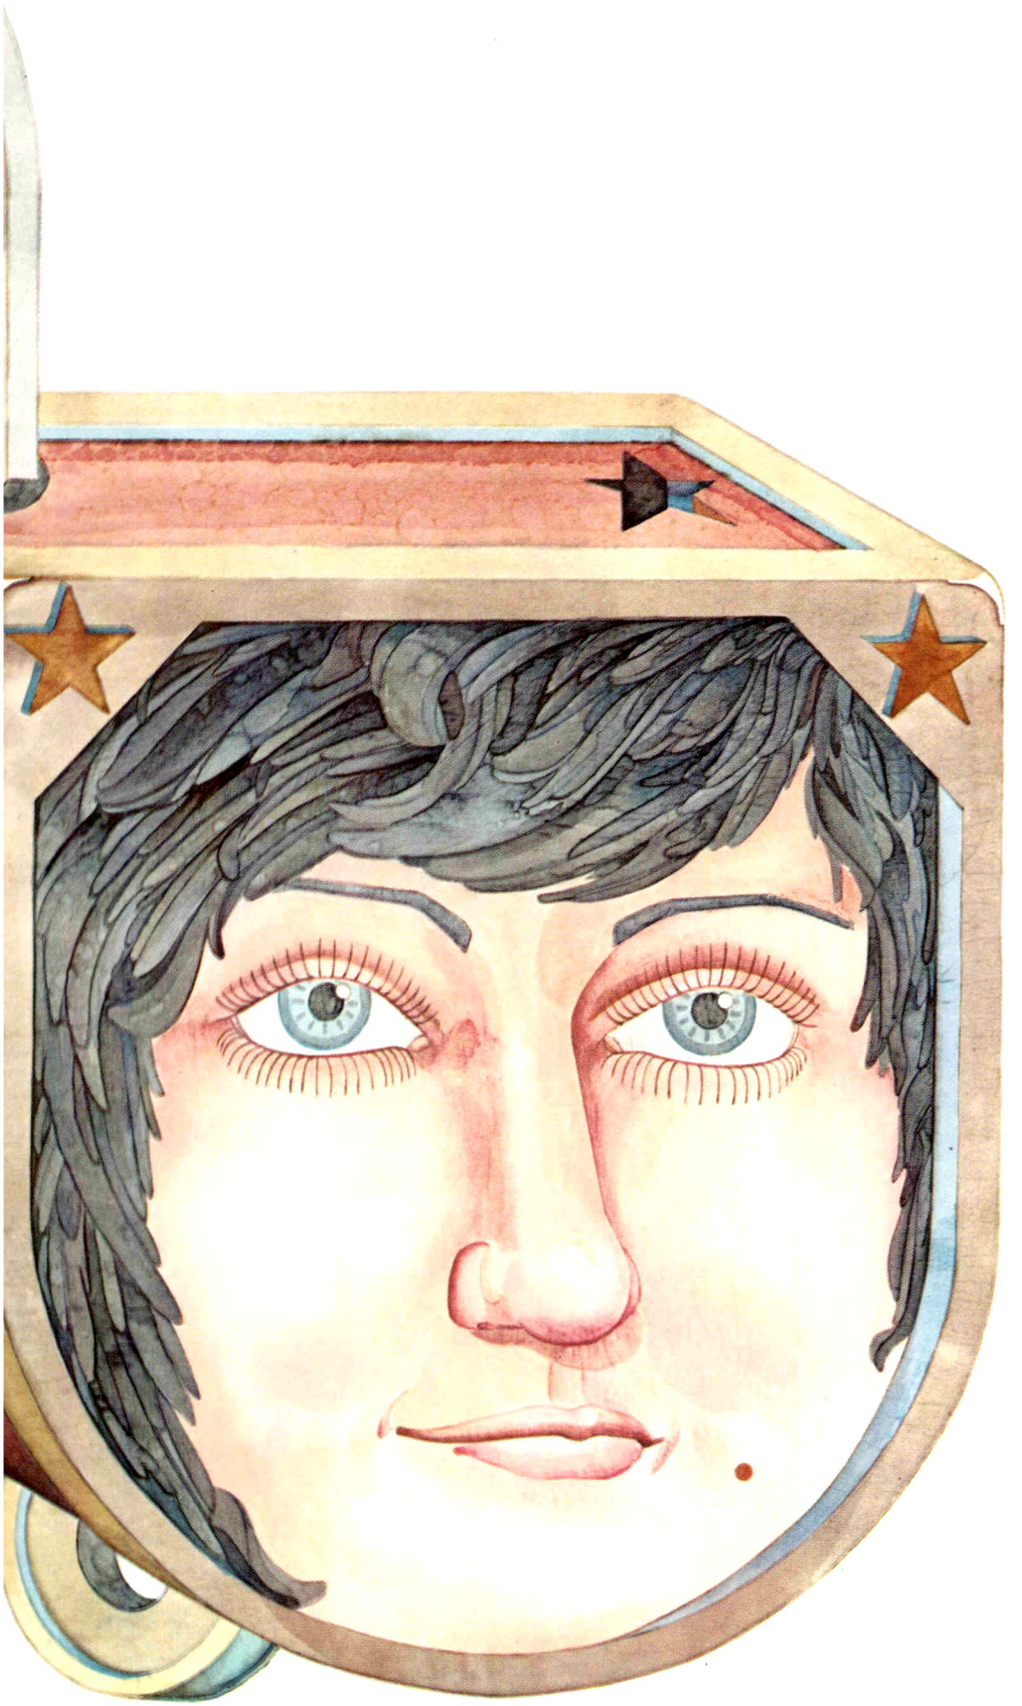
For more detailed information, consult your MSD representative or see the Direction Circular. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

MSD MERCK SHARP & DOHME

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.



In severe anxiety

Serax®

(oxazepam)

Wyeth Laboratories
Philadelphia, Pa. 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Persuasion & Healing

Jerome D. Frank

A Comparative Study of Psychotherapy

Selected by four major book clubs!
New, completely revised edition!

Jerome Frank's popular study of the healing powers of psychotherapy is a classic. It has now been completely revised and updated to take into account the many new developments in psychotherapy over the last decade, especially in research, behavior therapy, and group approaches.

Dr. Frank examines healing rituals, the so-called placebo effect in medical practice, and psychological experiments on the transmission of personal influence. He also considers contemporary forms of individual, group, encounter, and institutional psychotherapy.

Reviewing the first edition, *Contemporary Psychology* urged, "This book should be read by everyone who has anything to do with psychotherapy." You'll definitely want to read the new edition; it's even better! $12.50

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg. **Concentrate: 5 mg./cc.** **Intramuscular: 2 mg./cc.**

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg.
(thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 4 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc. contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v.

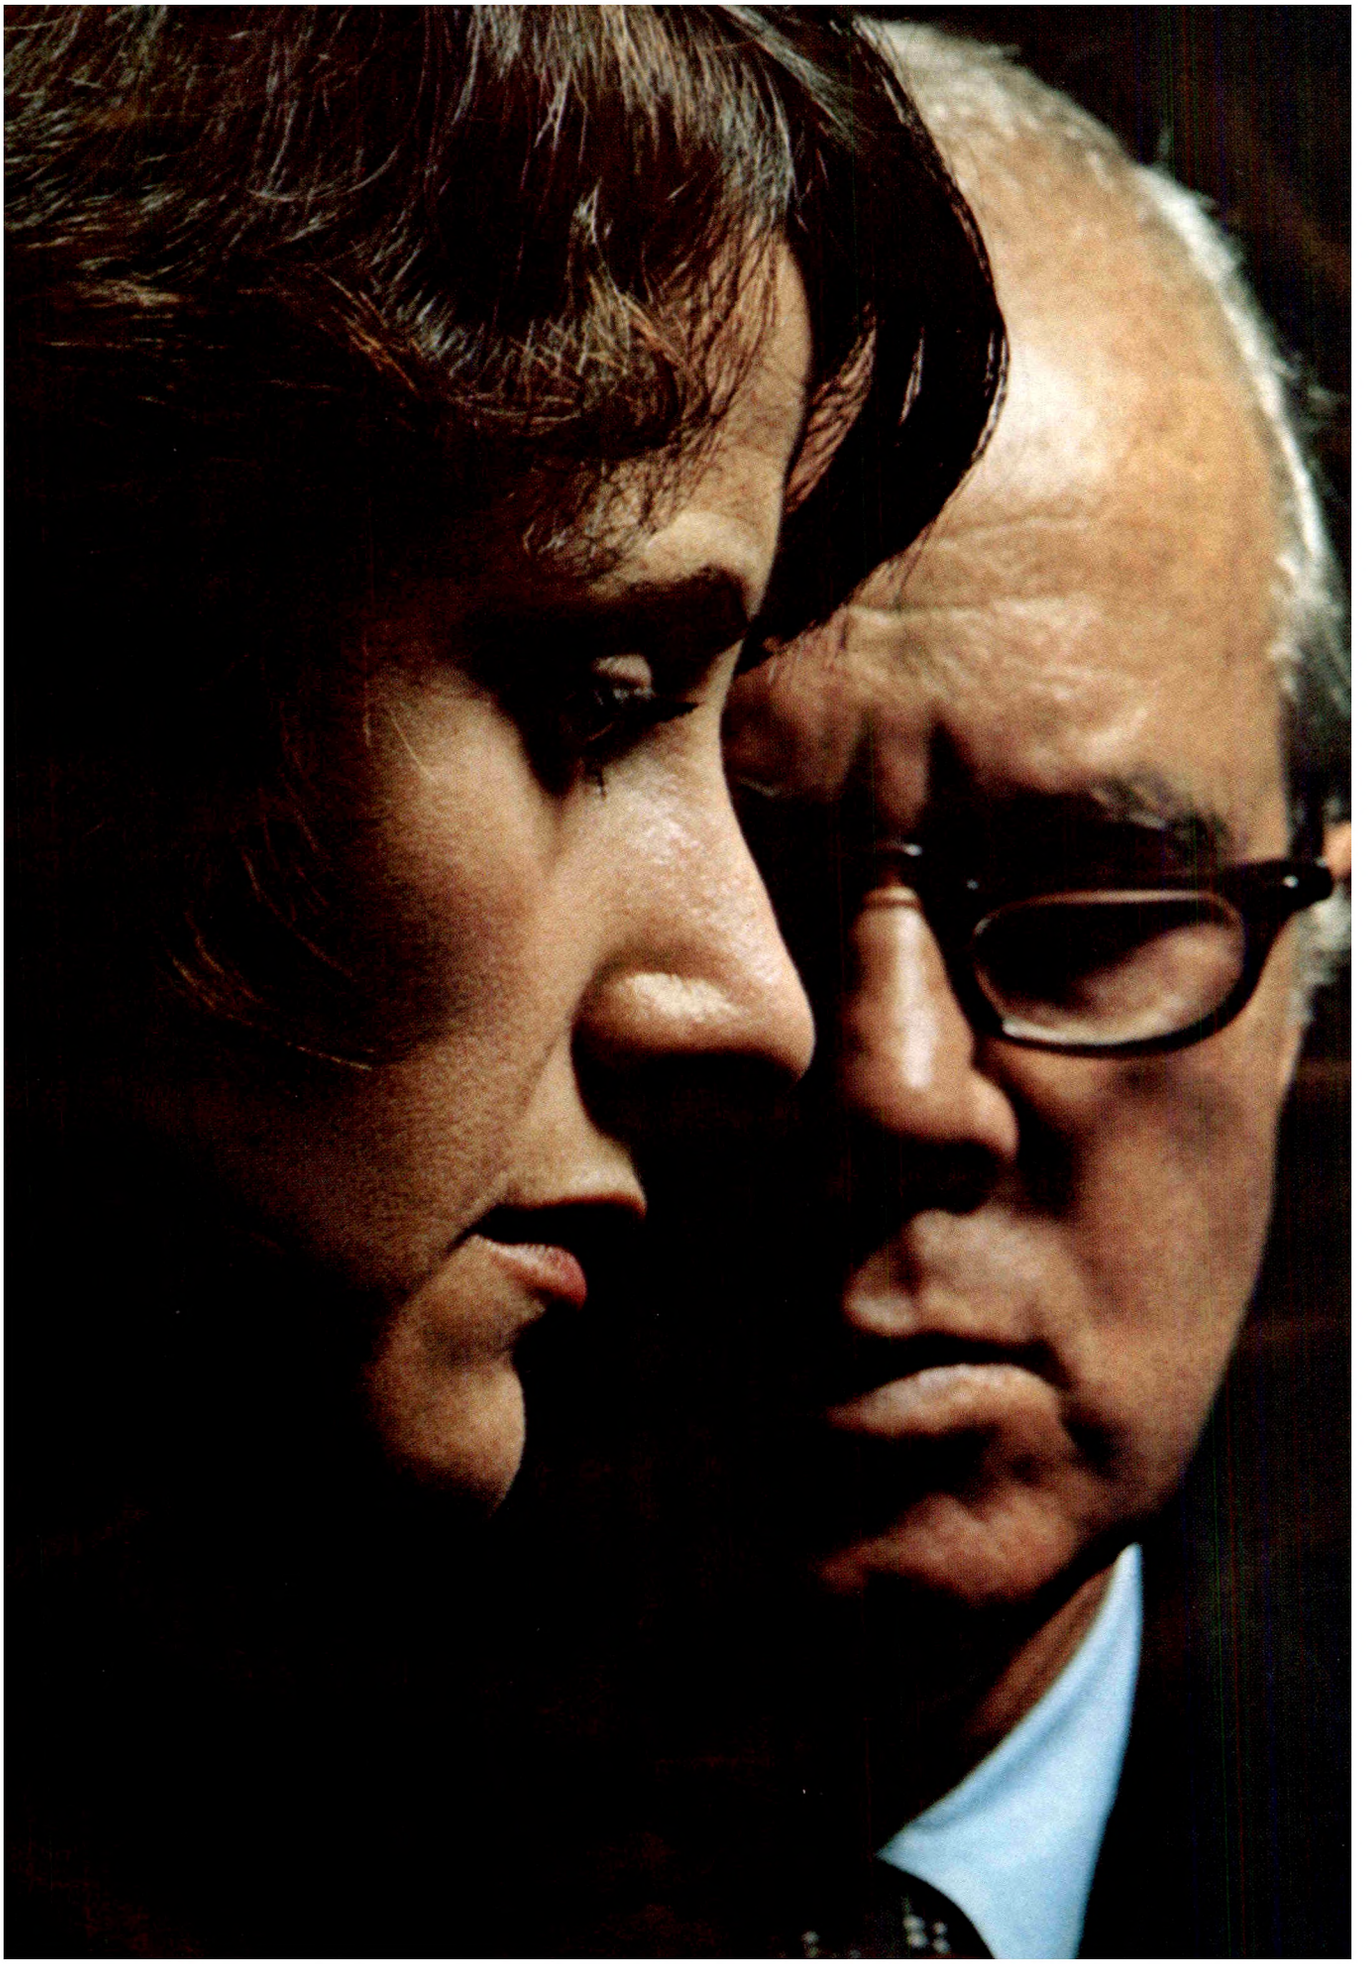
The Country Place

LITCHFIELD, CONNECTICUT

THE COUNTRY PLACE is a residential community for the emotionally disturbed adult who has more insight than he can use, who knows how he should act but withdraws from action.

THE COUNTRY PLACE offers
a home where he is understood
a work place where he can cope with the demands
a community where he can find social identity



THE COUNTRY PLACE
provides team work in socially useful projects
self help through interaction in groups
exploration of existent reality

THE COUNTRY PLACE maintains a well-trained professional staff for individual and group therapy psychodrama, art, dance and music therapy, as well as sports and games

WEEK END WORKSHOPS for professionals interested in studying our method of helping the disturbed person in creating a new identity

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

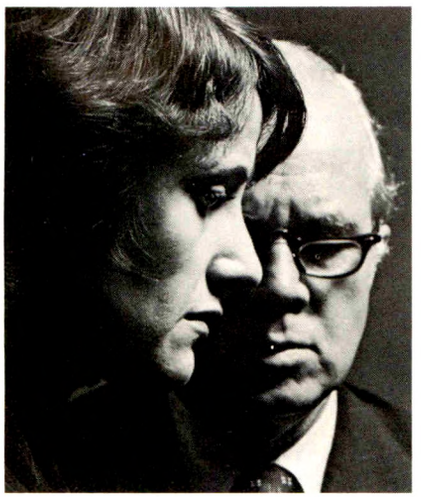
When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

MSD
MERCK SHARP & DOHME



For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible.
Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galac-

torrhea, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion; and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

For more detailed information, consult your MSD Representative or see full Prescribing Information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

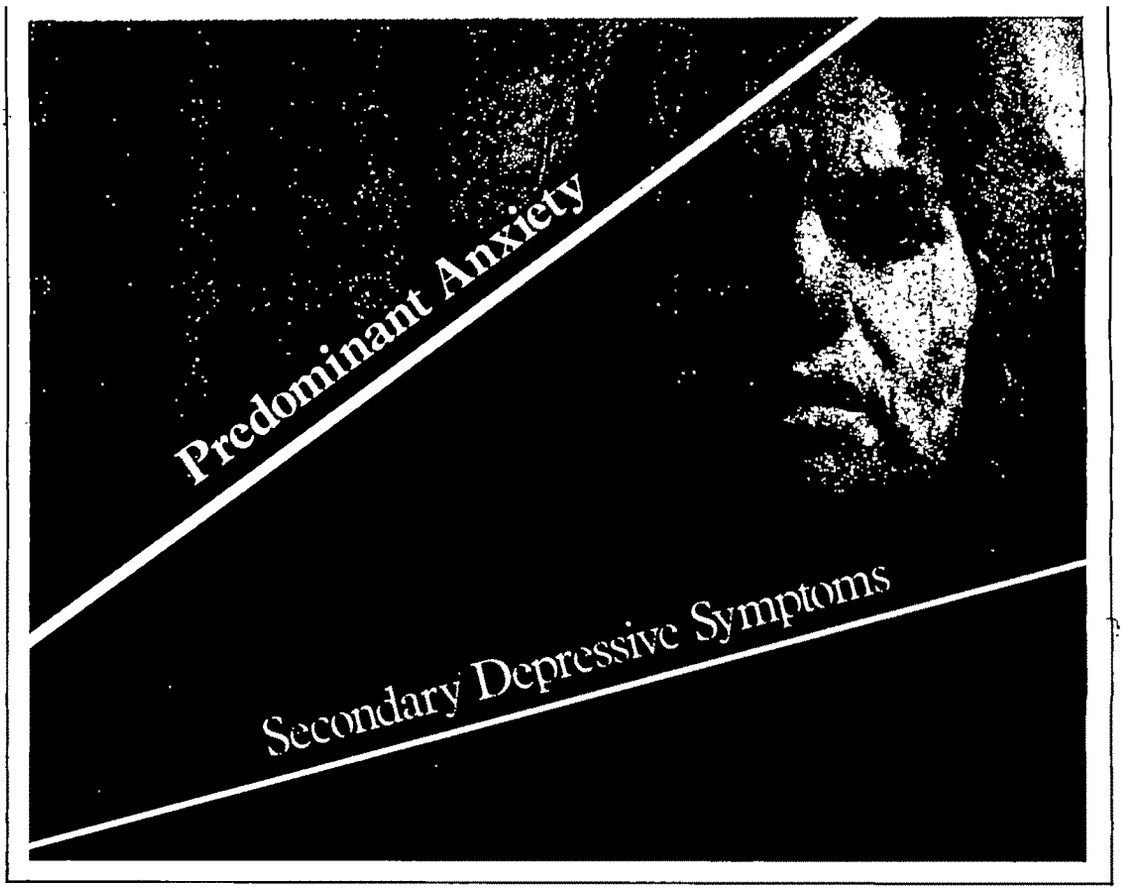
1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.



Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

This psychoneurotic often responds

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

When you determine that the depressive symptoms are associated with or secondary to predominant anxiety in the psychoneurotic patient, consider Valium (diazepam) in addition to reassurance and counseling, for the psychotherapeutic support it provides. As anxiety is relieved, the depressive symptoms referable to it are also often relieved or reduced.

The beneficial effect of Valium is usually pronounced and rapid. Improvement generally becomes evident within a few days, although some patients may require a longer period. Moreover, Valium (diazepam) is generally well tolerated. Side effects most commonly reported are drowsiness, ataxia and fatigue. Caution your patients against engaging in hazardous occupations or driving.

Frequently, the patient's symptoms are greatly intensified at bedtime. In such situations, Valium offers an additional advantage: adding an *h.s.* dose to the *b.i.d.* or *t.i.d.* schedule can relieve the anxiety and thus may encourage a more restful night's sleep.

symptom complex to Valium® (diazepam)

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

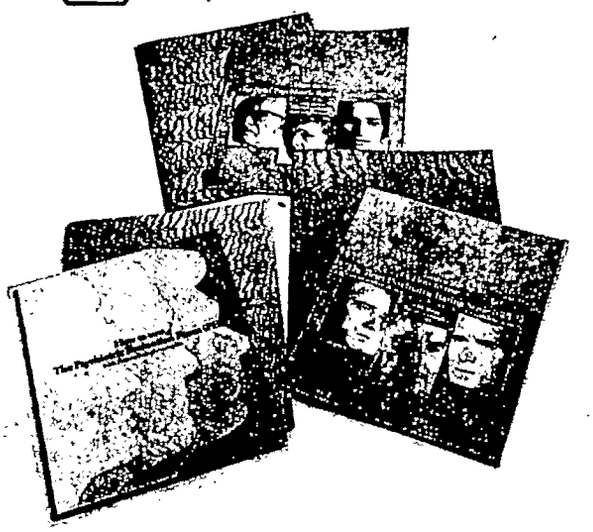
UNIVERSITY COLLEGE OF MEDICINE
LIBRARY

When you're working 27 hours a day...



. . . you don't have the time to find, and read, an average of 6,000 articles appearing each year in world medical literature. The Roche Psychiatric Reference Service (RPRS), through the resources of Excerpta Medica, helps you "keep up" with your special interests in the literature. The service allows psychiatrists to select one of eleven groups of topics that include the subjects of greatest interest. Approximately monthly, RPRS will send you concise abstracts of up to 30 papers in your special interest area.

All psychiatrists are invited to participate, at no charge.

. . . you can't always quantify your clinical records, increasing their significance while reducing their bulk. Roche has introduced a mail series on **Psychiatric Rating Scales.** Rating scales have gained widespread use, providing a common language for certain aspects of psychiatry by extending clinical evaluations into numerical terms. The series highlights clinical aspects of various scales that meet various needs.

Alfred PUBLISHERS

A Silent Tragedy

Child abuse, one of the ugliest crimes, is difficult to prove and frustrating to prosecute.

In A SILENT TRAGEDY – CHILD ABUSE IN THE COMMUNITY, Peter and Judith DeCourcy, professional psychologist and social worker respectively, document more than a dozen cases that were reported to police and eventually made their way onto court dockets. These cases include torture, incest, neglect, violence, and even murder.

The DeCourcys view abusive parents as having personality disorders – as poor candidates for rehabilitation – and call for reform in the courts and care of abused children. Their anguish and concern cry out at the turn of every page.

Read this book now. A child's life may depend on it.

To order your copy at $6.95, write Alfred Publishing Co., 1101 State Road, Princeton, New Jersey 08540. Attn: Mrs. Sidney Anderson. Or order through your local bookstore.

Child Psychiatry Residencies

New, Board Approved, Child Psychiatry Residencies offered in an innovative, established clinical program. Community Child Psychiatry, Day Treatment, Outpatient and Residential Treatment offer opportunities for a variety of treatment techniques. Crisis Intervention ("life-space" Interview); behavioral therapy, pharmacotherapy; individual, group and family treatment methods; dynamic, social and developmental psychiatry taught. Learning by independent study, seminars, supervised experiences. Multi-disciplinary staff including; six child psychiatrists, pediatrician, pediatric neurologist, psychologist, social workers, special education teachers, speech therapists, occupational therapist, recreational therapists, etc. Program affiliated with the University of Michigan and a variety of clinical settings including; community mental health centers, guidance clinics, etc. Salaries negotiable.

when anxiety and depression travel together through the pathways of the neurotic mind*...

Mellaril®
(thioridazine)

TABLETS, 25 mg. and 50 mg. thioridazine HCl, U.S.P.
Usual starting dosage: 25 mg. t.i.d.

*Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified this indication as "probably" effective.
Final classification of the less-than-effective indications requires further investigation.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: ***Central Nervous System***—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. ***Autonomic Nervous System***—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. ***Endocrine System***—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. ***Skin***—Dermatitis and skin eruptions of the urticarial type, photosensitivity. ***Cardiovascular System***—ECG changes (see ***Cardiovascular Effects*** below). ***Other***—A single case described as parotid swelling.
The following reactions have occurred with phenothiazines and should be considered: ***Autonomic Reactions***—Miosis, obstipation, anorexia, paralytic ileus. ***Cutaneous Reactions***—Erythema, exfoliative dermatitis, contact dermatitis. ***Blood Dyscrasias***—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. ***Allergic Reactions***—Fever, laryngeal edema, angioneurotic edema, asthma. ***Hepatotoxicity***—Jaundice, biliary stasis. ***Cardiovascular Effects***—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. ***Extrapyramidal Symptoms***—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. ***Endocrine Disturbances***—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. ***Urinary Disturbances***—Retention, incontinence. ***Others***—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

SANDOZ

THE AMERICAN JOURNAL OF PSYCHIATRY

Overview: The Impact of New Advances in Sex Research on Psychoanalytic Theory

BY ROBERT J. STOLLER, M.D.

This overview describes five concepts of sexuality that run through Freud's writings—bisexuality, infantile sexuality and the Oedipus complex, libido theory, the primacy of the penis, and conflict—and tests each against recent advances in sex research.

PSYCHOANALYTIC THEORY is Freud's creation; most modifications introduced by others have not only been minor but are elaborations of theoretical positions he had already explicitly introduced. It is therefore understandable if this presentation examines the sexual theories of Freud alone. This permitted, I need only add that, while one cannot usually discuss any sector of his work without remembering how it changed as the years passed, this is less true for his sexual theories.

I would like to focus my discussion almost completely on the two areas of behavior for which the term "sexual" is commonly used: the search, originating in the drive toward reproduction, for erotic pleasure and the development and maintenance of masculinity and femininity. This overview is based on five concepts of sexuality that run through Freud's writings from almost the beginning of his great work—before and after 1900—to his death and will test each against recent advances in sex research. The five concepts are bisexuality, infantile sexuality and the Oedipus complex, libido theory, the primacy of the penis, and conflict. While each is interwoven with the others in making up his coherent theory of sexuality, I will separate them for ease of discussion. In doing so, I will emphasize the "impact" more than detailing the "new advances."

This paper was written at the invitation of the Editor; it is largely based on a paper read at the Auken Conference, Copenhagen, Denmark, May 4, 1972.

Dr. Stoller is Professor, Department of Psychiatry, UCLA School of Medicine, Los Angeles, Calif. 90024.

CONSTITUTIONAL BISEXUALITY

Freud felt there is a biological substrate—the "bedrock" (1)—of bisexuality,[1] upon which all later psychological development is anchored. Where are we nowadays with this concept that there is a biological bisexuality, and where are we with the related idea that such a "force" is an essential effector of human behavior, normal and pathological? I think most of us today believe in something like Freud's biological bisexuality (now more stylishly called "sexual bipotentiality" or "sexual dimorphism"); we know that cells, tissues, and organs in each sex can be modified in the direction of the opposite sex. Most of us, however, would not look on these findings as quite indicating bisexuality as Freud understood the term.

Especially following Jost's embryological work (most recently reviewed in Jost [2]), the evidence has piled up that, in mammalian species at least, the "resting state" is on the female side and that to make tissues, organs, or organisms male requires an androgen pulse (apparently initiated by the Y chromosome) for the development of each of those anatomical and physiological criteria whose algebraic sum we call maleness. Even, and especially, the brain requires such masculinization in mammals, or else masculine behavior will not result.

Our expectation that we shall find that humans share in the general rule of the femaleness of mammalian tissue seems borne out when we look at the "natural experiments" of endocrine disorders. There we see in each instance that the fetus that is deprived of androgen at critical times in its development fails to show anatomic maleness, regardless of chromosomal sex. The XO

[1] Freud used "bisexuality" in several ways, ignoring distinctions in order to arrive at the highest level of abstraction. Thus we are often uncertain whether he means a prime principle of all living cells, a state of anatomical affairs in the embryo, anal pleasure in the child, friendship between people of the same sex, overt homosexuality, or a universal attribute of human sexuality. He felt they are all aspects of the same concept; I do not.

(Turner's syndrome) infant, whatever her defects, has no male tissues, for she had no gonad to produce androgen and, in the androgen insensitivity syndrome, the inability of target tissues to respond to circulating androgens restrains fetal development to femaleness. On the other hand, the female fetus that is exposed to increased androgen, as in hyperadrenalism, is masculinized and, in the extreme case, the clitoris is anatomically indistinguishable from a penis.

But none of this touches on psychoanalytic theories of behavior per se, except to indicate, as Freud had already been taught, that the male organism's tissues can be as if female, and vice versa for females. Freud's interest as a psychologist was not, however, in these anatomic matters but in the mind-body problem: How do these physiological matters affect behavior? Here we are especially indebted to Money, whose studies on people with such endocrine disorders as those mentioned above suggest that the fetal human brain also needs to be "primed" with androgen for normal masculine development and that, if the female fetal brain is exposed to androgens, a mild though measurable increase in masculine behavior in the growing girl can be expected (3). Other studies suggest that an unusual number of males with congenital hypogonadism, and thus presumably inadequate fetal androgen (for example, as in Klinefelter's syndrome), are feminine from earliest childhood on, regardless of rearing (4, 5).

Recent reports have suggested that homosexuality in males is caused primarily by biological forces. Geneticists have argued that homosexuality is inherited (6, 7). One worker has described the instant cure of homosexuality by neurosurgery (coagulation of Cajal's nucleus in the ventromedial hypothalamus), indicating a precise brain center for the behavior (8, 9). Other studies have shown decreased plasma testosterone levels and impaired spermatogenesis (10) and an abnormal ratio of androsterone to etiocholanalone (11) in direct relation to the degree of homosexuality. None of these studies contradicts the others; they may be measuring different aspects of the same process: genes, neuroanatomy, or chemistry. And none necessarily contradicts psychoanalytic theory, if each is a piece of the underlying "bedrock" to which Freud referred. However, if the claim is made that these biological mechanisms are *the* cause of homosexuality, then of course Freud's theory of disturbed interpersonal relationships (oedipal and pre-oedipal conflict) is in doubt.

But as yet I do not believe these physiological studies, animal or human, explicate human sexual behavior; I think, rather, that they tell us only about underlying biological *potentialities*, as do so many other studies in regard to an aspect of human behavior. (An epileptic seizure tells us something about aggression and violence, as does a decorticated cat, but it does not tell all.) As usual, what is made of those potentialities usually lies in the area of environmental influences. For help in this regard, let us turn to the theories of interpersonal object relations and of social learning.

INFANTILE SEXUALITY AND THE OEDIPUS COMPLEX

Freud believed bisexuality (and all sexuality) arose from two sources: the first was biological (as we have already seen), a fixed part of human psychology, and the second was environmental. He said (12) what most of us believe: the importance of the biological or the environmental in determining sexual behavior varies from person to person and from time to time. While his great finding was the power of the environment ("the accidental factor"), his grandest theories were about biology. Feeling that all his psychoanalytic theories were ultimately biological, he did not adequately differentiate between biological philosophizing and the rigors of biological research. The former should be ignored (although, unfortunately, it has been the basis of the fiercest battles within psychoanalysis, e.g., the concept of psychic energy, life versus death instinct, libido theory, Lamarckian inheritance of past experiences of the human race), unless analysts are also willing to do the scientific work necessary to defend these theories.

In fact, on putting aside Freud's "biologizing," we find his contributions, which now stand clear, perhaps even more formidable. One of the greatest of these has been his emphasis on infantile and childhood sexuality. He underlined the crucial importance of parent-child relationships (which I will look at shortly when discussing the Oedipus complex) as a cornerstone of his work almost from the start. What Freud undertook, as early as 1900 (13), was the most powerful and explanatory social learning theory of human development ever proposed.

Over the decades, his biological speculations have not been confirmed. His interpersonal theories and his observations of parent-child interactions, however, have been a rich source for innumerable researchers to the present (including, to their shame, many who refuse to acknowledge his gift to them), and many of their fundamentals have not been refuted.

Freud told us, as no one did before, that parents have the greatest possible influence on their children's development, that children create their psychic structure in response, that adult sexual life can be traced back to effects in infancy, and that sexual desire and gratification find their origins in infancy, long before the obvious upsurge of puberty. Exactly how parents transmit these influences to their children has been the subject of increasing study by analysts and nonanalysts for years. Freud's ideas spurred the researches of physiologists, behaviorists, ethologists, general systems theorists—innumerable workers who now believe infancy and childhood are crucial developmental phases.

Social learning theorists (as they are called in academic circles) or object relations theorists (as they are known among psychoanalysts) have, of course, great theoretical differences. These may obscure an overriding similarity: the belief that behavior can be radically modified purely by the effects of one person upon another. These workers also share the belief that the personality of the infant and small child, more than that of the adult, is

especially vulnerable to permanent behavior modification. Their major area of disagreement may be over the question of whether trauma, conflict, defense, and compromise formation as a resolution of conflict contribute fundamentally to personality formation.

We must here separate two different aspects of sexuality. The first is that concerned with genital pleasure, which is more or less tied to reproductive behavior or its avoidance, and the other is gender behavior, which is related to masculinity and femininity. Here again I wish to emphasize the danger of extrapolating from animal to human behavior, even if such caution is currently unstylish. Of all the areas of behavior in which there is discontinuity between animals, even primates, and man, the greatest is in motivated behavior. The evolutionary rule is not only that certain fundamental behaviors persist, tied to neuroanatomic structures and circuits that are constant across species, but also that the higher one goes in the evolutionary scale, the greater the amount of choice available to the organism.

The brain substrates of what we call "choice" or "freedom" simply do not exist in any other creature as they do in man. No one seriously argues about whether man has a greater potential for variability of behavior than any other animal or whether man's behavior, even in its neurophysiological roots, requires more priming (organization) by environment than that of any other animal. For instance, we can search the evolutionary scale forever to find the biological roots for aggression but from that source we cannot determine why man is the only species that murders his own kind. Perhaps some day we shall find a thalamic focus for penile erections in man as in monkeys (14); that sort of behavior—the fundament—obeys evolutionary rules. But there is an entirely separate level of behavior that is much more complicated, though the final action is simple and physiological—say, erection. The input leading to this latter behavior is not only thalamic or hypothalamic but goes through the unknown neurophysiology that is the result of previous experience fixed in memory and modified by fantasy (especially unconscious fantasy). It is unique to man. Man remembers differently from other animals: *he symbolizes and he fantasies*, and in that way he not only remakes the past but invents the future he anticipates.

In closer relation to our subject, the evolutionary perspective has failed to teach us much about human sexual desires, object choices, or pathology. For instance, the perversions—habitual, driving needs for aberrant genital satisfaction—are not found in free-ranging members of lower species, but they are ubiquitous in man. The puny attempts to demonstrate perversion in lower animals (e.g., the cows that mount other cows are homosexuals) are not edifying.

Similarly, studies that reveal the types of distortions of behavior that can be permanently built into animals by experiments (e.g., conditioning, imprinting, or implanting electrodes in discrete brain structures) tell us about potentialities but do not give us answers about free-ranging behavior in man; the data only show us more questions we should ask. In other words, these findings in animals confirm nothing in humans; they only suggest. However, it is important for analysts to recognize that, when theory building, they ignore such suggestions at their peril.

Parent-Child Relationships

For Freud, sexual development depends strongly on relationships between parents and their children—the Oedipus complex. Let me forego an adequate review of this hypothesis as it relates to masculinity and femininity and recall only that Freud said boys have two great advantages over girls: a boy's first love is heterosexual because his first love object (mother) is female and, secondly, he has a superior phallus. His masculine development is threatened mainly by the fear that his desire for his mother will anger his too-powerful father; excessive fear may damage his masculinity. On the other hand, the girl, in her attachment to her mother, starts life with a homosexual relationship, and only on relinquishing it and her belief that she will have a penis will she become feminine and turn to her father.

Because Freud saw this process as more conflict-laden and devious in girls, he felt he had an explanation for his conviction that adult female sexuality is less certain, less gratifying, and more mysterious than that of males. A curious addition to his theory was his belief that the development of little boys and little girls is about the same [2] until the onset of the full-blown development of the oedipal situation (at about age five or six) and that therefore no significant, true femininity is present in little girls before this age.

Some workers (e.g., Malinowsky [16]) have claimed the Oedipus complex is imaginary because its form is different in some societies, e.g., the genetic father's place as the psychological father is taken by one of the mother's kin. But so far, there are no descriptions of cultures in which the growing child is not looking upward toward a large and powerful male who serves as a model for masculinity for boys and a model heterosexual object for girls, or toward a female who mothers. What varies from family to family and culture to culture is how much conflict there is in the complex, but not whether families are made up of mothers, fathers, and children, each with attributes of power and sex more or less as Freud noted in Vienna.

Where is this theory of the development of masculinity and femininity at present? A new factor has been thrown into the discussion by studies on the earliest stages of gender development, which contradict Freud in several places. It was found that certain boys, because of an oddity in child-rearing practices, were markedly feminine from their earliest days on. They were found to have spent excessive time in intense, blissful intimacy with their mothers, and the mothers who are more likely to create this type of situation are drawn to marry distant

[2] Freud wrote: "Both sexes seem to pass through the early phases of libidinal development in the same manner. . . . With their entering into the phallic phase the differences between the sexes are completely eclipsed by their agreement. We are obliged now to recognize that the little girl is a little man" (15, pp. 117–118).

and passive men. In general, the purer the form this constellation takes in a family, the earlier and the more ingrained and irreversible is the femininity that develops in the boy (17). On the other hand, boys who have close relationships with their fathers are found not to have mothers like this, and the boys are masculine (18).

A girl who has a distant, unloving mother but whose father is close to her develops masculinity if the father encourages her to have the same interests he does (19). A girl whose mother enjoys having a daughter and is not ashamed her daughter has a female body, and whose father encourages his daughter's femininity, will grow up feminine (20).

Whether the communications between each parent and the infant mold the child's behavior by imprinting, classical or operant conditioning, identification, or combinations of all these is still to be thrashed out. What is demonstrated in study after study, however, is that the attitudes communicated from parent to infant are powerfully instrumental in creating masculinity and femininity in both sexes. This reduces the conflict (castration anxiety) aspect of gender development; unlike Freud's theory, conflict-free development plays a prominent part in this description.

A greater disagreement with classical analytic theory arises from the above. While it is obvious enough that the boy's first love object is a female (his mother), in his earliest stages of life a great physical and emotional intimacy (merging) between him and his mother's body and psyche introduces the risk of identification with a female.[3] And so, one of the boy's first tasks on the way to masculinity is to separate himself from his mother (21); that process can be subverted by a too-loving mother. The same intimacy does not thus endanger the little girl, for such closeness with the mother only encourages her femininity.

New data are appearing in regard to the differential handling of male and female infants by their mothers (22); in the usual case (which is more likely to produce femininity in girls and masculinity in boys), girls have more contact, physical and visual, during the early months than boys (23). Mothers generally feel easier being intimate with their infant girls than with boys. Therefore the boy does not have the straightforward heterosexual development Freud alleged. Instead, he has a major impediment on the way to heterosexuality; he must rid himself of whatever femininity may develop in the mother-infant symbiosis. Only then, at a later stage, can he see his mother as the separate and desirable object of the classical oedipal situation (24).

And so, rather than girls being little boys, the above would predict that little girls are shaped in the direction of femininity right from the start. And that is what simple observation reveals: girls in general just are not masculine in early childhood. Clear-cut femininity is routinely seen by a year or so of age; there is no evidence this is a facade or an imitation of femininity. How can I agree with this statement of Freud's: "As we all know, it is not until puberty that the sharp distinction is established between the masculine and feminine character" (12, p. 219)?

[3] "Identification" is used here with caution; as hinted above, the intimacy may influence the boy by less cognitive processes (e.g., imprinting) than "identification" connotes.

THE PRIMACY OF THE PENIS

Freud accepted as a given the belief that the superior sex is male. He felt this was a fact established throughout mammalia by males' physical superiority in strength: life-or-death struggles select males as superior because they are stronger. This fact, with the penis as its most compelling symbolic representation, was then reflected in mythology, folk tales, institutions of society, artistic productions, religious worship, dreams—everywhere.

In the family such power was granted to the father not only because custom demanded but because, from ancient times, it was his accepted responsibility to protect his family from physical danger and to provide food and at least minimal comforts, and because, as the strongest member of the family physically, he had life-and-death control over each member. This power, ultimately derived from the reality of physical strength, was institutionalized in society, from the ruler down into the family.

Freud, coming from a culture in which this authority still manifestly resided in fathers, did not have to question his principle that "anatomy is destiny." Any theory, however, in which this idea is an essential building block is weakened if the principle is incorrect.

Freud's enthusiasm for the position that men are superior fitted with what he considered observable fact: that women are secretive and insincere (12, p. 151); are more masochistic (15, p. 116), less self-sufficient (p. 117), more dependent and pliant (p. 117), and more envious and jealous (p. 125); have defective superegos (p. 129) and little sense of justice (p. 134); are more bisexual (p. 113), more narcissistic (p. 132), and weaker in social interests (p. 134); have less capacity for sublimating their instincts (p. 134); and are more rigid and unchangeable at an earlier age (pp. 134–135). They are intellectually inferior because they are biologically created for the nonintellectual task of motherhood; they are morally inferior because, lacking a penis, they cannot easily be threatened and because they are bound more concretely to the real world and so are less concerned with such aesthetic issues as morality (that is, they obey the command of biology rather than a more ethereal call).

It is a corollary of the thesis of male superiority that the prime feature of maleness, the penis, is a superior organ physically and symbolically; and Freud could point to phallic worship, in its myriad forms, for proof for those who do not listen to the dreams of men and women. In the concept of castration anxiety he found reason to believe that men considered the penis the prime organ of the race, and in penis envy, he found the proof that women also agreed on the primacy of the penis. Because it is visible, can change so in size, is shaped like a weapon, can penetrate, frightens women, and is such an intense

source of sensation from infancy on, it also demonstrates its superiority. Then, when it is contrasted with the female genitals, the case is again made. The female phallus, the clitoris, is much smaller, not visible, cannot penetrate, has not seized mankind's imagination, is never symbolized or exalted, and—Freud thought—is not a competent source of pleasure. Its significance is further weakened since it must share its fate with another organ, the vagina, which Freud felt was universally considered an inferior organ—it is hidden, dark, mysterious, uncertain, unclean, and an undependable source of pleasure.

That is a lot of evidence; wherever Freud looked in the outer world or in mental life, the primacy of the penis seemed proven.

Offered against Freud's argument is the exciting new research alluded to earlier. In mammalian species the function of cells is female in both sexes, until androgens are added in fetal life. In fact, except for the chromosomes, one cannot talk about two sexes until the androgens have been added; there is only femaleness. Freud, who always had a nose for mystery and who found so many of his mysteries at the most fundamental levels—cell function or even more primitive levels—would have been nonplussed by the above finding. And even more would he have been disturbed in his argument to learn that this female character of tissues extended into the central nervous system, where, as has now been demonstrated in mammals other than man, future masculine behavior in the male requires the organizing only androgens produce, while in the female nothing need be added for femininity. The new research would therefore seem to put Freud's argument in a most precarious position and, since he chose to extend his beliefs from the realm of psychodynamics into morality and other cosmic issues, in the last few years he has been well beaten about the head.

Nonetheless, we have not yet found in the new data a proof that mankind does not believe in the primacy of the penis; one can still ask where in the child's psyche this knowledge of embryology or tissue capability resides. It is not to be found. But we easily detect boys' and girls' attitudes about penises; they still find them impressive. Is this primacy? Some no longer think so but instead feel it is too bad Freud did not emphasize more strongly that children of both sexes are also deeply stirred by the significance of breasts and the womb; reproductive power is more difficult to represent visually, but, if measured by the mystery it creates, it is more important even than the penis.

In addition, the observations of Masters and Johnson (25) have had a great vogue in diminishing Freud's ideas about femininity. He said a girl is masculine until she gives up her hope for a penis; as long as she hopes, however, she retains her fixation on her clitoris, as if it were a penis. Only if she shifts her eroticism to the generative inner space, the vagina and pelvic organs, will she be feminine. But Masters and Johnson have found that all female orgasms originate in the clitoris [4]; they have not observed vaginal orgasms. So Freud's argument seems disproved.

And I believe it is—but not at all by Masters and Johnson's work. Innumerable women have sensed they have two sorts of orgasms—one clitoral, the other vaginal; they have no trouble distinguishing the two. Just because gross vaginal changes at the moment of orgasm are not visible to these observers does not prove the absence of vaginal orgasm. Perhaps its physiology—as in the case of intense pain or itch in muscle or skin—is only not *grossly* visible; or perhaps vaginal orgasm requires penile intercourse with a meaningful man and is not producible in a laboratory; or perhaps there is so much action in the vagina at the moment of an orgasm produced by penetration that the view is obscured. Their work has not disproved that there is an orgasm experienced deeper in the body than is a clitoral orgasm. So that argument does not dislodge Freud, but another does: too many feminine women have been known who do not have vaginal orgasms (26) and too many do who, by Freud's definition of maturity, cannot be feminine—schizophrenics, neurotics of all types and degree, and even grossly masculine women.

But this is a nonscientific discussion masked by pseudo-scientific rationalization (27, 28). How can one prove one sex is superior to the other if one does not first state the categories to be measured? If superiority is measured by body size, phallic dimensions, skill in football, fatherliness, or production of sperm, females are unequivocally inferior; the differences can be measured. Likewise, if superiority is measured by size of bosom, gestational capacity, longevity, resistance to illness, motheringness, or capacity to ovulate, women have the unquestioned edge. In the middle lie innumerable skills at which neither men nor women inherently excel, such as weaving, growing rice, solving problems in psychoanalytic research, running an advertising agency, or bickering. And then there are such imponderables as: Is a woman superior if she can have limitless orgasms or is a man superior if he is completely satisfied after one or five? This sort of foolishness, so intensely argued these days, proves nothing. Instead of pontificating about superiority, we might simply try to observe the development of males and females and masculinity and femininity. Let us relieve ourselves of the burden of deciding which is the better sex.

LIBIDO THEORY

Libido theory is part of Freud's generalized theory of instincts. It is not my purpose to review the development and changes of this theory, but it will be recalled that he started with the traditional division of self-preservative and species-preservative and ended with the more mysti-

[4] No one seems to remember that Freud also said: "When at last the sexual act is permitted [for the first time] and the clitoris itself becomes excited, it still retains a function: the task, namely, of transmitting the excitation to the adjacent female sexual parts, just as—to use a simile—pine shavings can be kindled in order to set a log of harder wood on fire" (12, p. 221).

cal life versus death instincts. I shall not concern myself here with the scientific and epistemological questions raised over the years about the concept of instinct (or drive); instead, I wish only to discuss libido theory, that description of the maturation of sexuality as a movement and elaboration through stages, each of which has its focus on a different part of the body. In addition to the theory of object relations embodied in his description of the Oedipus complex, Freud saw a development, governed by an inherited timing mechanism, in which in all humans "psychic energy" converges in a part of the body, "cathecting" it with "libido." (I do not have time—70 years was not enough—to discuss the pros and cons of the concept of "psychic energy," nor need we be concerned here that neither "cathexis" nor "libido" was ever defined in scientific terms.)

The inexorable progress of libidinal development starts with the oral phase, wherein the infant's life-preservative, affectionate, and sensual drives center in the mouth and its functions. Next is the anal phase, with its pleasures of expelling and retaining feces (and urine), and then the phallic phase in which boy and girl focus on their intense penile or clitoral sensations and note their anatomical differences. The final libidinal phase is genital maturity, consisting of loving and genitally gratifying heterosexual relations, reached only by those fortunate few who surmount the oedipal conflict. To this theory of libido, a conceptual groundwork for all human psychology, was added an important corollary—that different emotional disorders took their origin from two sorts of disturbances occurring at one of these libidinal phases: fixations resulting from excessive gratification during a particular phase or regression, due to anxiety, from a more advanced to an earlier phase. This special theory is mentioned now only because Freud based his theories of the production of perversions particularly on the libido theory's description of sexual advance from zone to zone.

As a description of human childhood development, Freud's observations on zonal phases have been confirmed and can be confirmed at any time with biologically normal children. However, no studies have been published that confirm the implications drawn from the observations. It has not yet been shown that any class of neurosis, including the perversions, or psychosis is caused by a disruption of the sensual experiences of the mouth, the defecatory or urinary systems, or the phallus (29, 30). (There is, however, a great deal of evidence that disturbed *object relations* during these phases cause psychopathology.) Libido theory as an explanation of neurotogenesis has been so far off base that it has never attracted serious attempts to test it by scientific methods.

An odd piece of libido theory is the notion that libido is a quantitative energy that flows or can be dammed and that the function of the "mental apparatus"[5] is to reduce the "instinctual tension"—unpleasure—that results from such damming. True, people usually get pleasure from tension reduction, as with sleeping, or after eating, intercourse, excreting, affect discharges, skin scratching, etc. But is that an effect of the postulated libido? Being a neurophysiological construct, libido can be challenged by a neurophysiological model. As it turns out, libido is as hard to seize as were the other "humours" of past eras. Rather, mammals (31), including man (32), have a precise center that produces the subjective experience called pleasure. Experimentally, it does not deplete as if drained. It can be turned on and off endlessly so that an animal can experience the same degree of intense pleasure even thousands of times an hour (31). The most parsimonious explanation of pleasure at present is not the hydraulic one of the flow of a substance or energy; the energic requirements of a switching mechanism in the central nervous system are infinitesimal.

CONFLICT

Two types of painful situations can influence personality development and thus sexual development, through severe impingements on the infant by events not felt as part of its psyche. These events may be unpleasant internal sensations (such as hunger, body pain, or respiratory distress) or external events (struggles against frustrating or traumatizing objects separate from one's body, intermittently by inanimate objects and persistently by important people, especially the mother at first). These are traumas (acute, chronic, or cumulative). Not all produce conflict; conflict implies intrapsychic struggle in order to *choose* among possibilities. Trauma may only cause reaction (change). For instance, early in infantile development a stimulus may produce change without conflict by an ethological process like imprinting, by classical conditioning, or by operant conditioning. But Freud did not believe trauma caused perversion of sexual development until it caused conflict; conflict is the awareness of the need to choose between alternatives and requires a development advanced enough that memory, judgment, and perhaps fantasy are beginning to influence one's behavior.

His theory of the causes of perversion[5] (as with all sexuality) is a combination of the five categories we have been considering: bisexuality, the Oedipus complex, the primacy of the penis, libido theory, and conflict. Granted that there are variably powerful diatheses, such as inherited bisexual tendencies or an unusual constitutional capacity for pleasurable sensation in a part of the body other than the genitals, he felt that, above all else, it was infantile conflict—castration anxiety, pre-oedipal and oedipal conflict, fear of heterosexuality—that changed

[5] I am retaining the quaint word "perversion" (rather than using the more neutral terms "variant," "deviation," or "aberration") for the habitual, preferred, compelling need to perform an erotic act when the deviant act arises from severe anxiety and the act protects the person from the source of anxiety. This implies that there are both perversions and variants—the latter not the result of such anxiety. Freud's theory, incidentally, seems to leave no room for the idea of a sexual aberration that is not also a perversion, i.e., a habitual aberrant erotic act that is not the product of conflict: "We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism" (12, p. 231).

normal sexuality into perversion.[6]

Sexual deviance (perversion or nonperverse variance) leading to orgasm is almost never seen in animals (unless they have been manipulated by unnatural forces, such as experimentation or captivity). On the other hand, such needs are ubiquitous in man; sexual deviance is as exclusively human as are murder, humor, fantasy, competitive sports, art, or cooking. This observation is so grossly manifest that one wonders why it has no force in the speculation of modern sex researchers. *Almost every notable study on human sexual behavior since Freud has tried to prove that one does not create his own deviance* but rather that it is thrust on him—by genes, by hormones, by electrical circuiting in the brain, by imprinting, by conditioning, by statistics. How Freud has disturbed us! We still cannot bear his "accusation" that we are humans.

Will someone please explain pedophilia in geneticists' terms? Or shoe fetishism as a product of a brain mechanism constant through evolutionary development? Or penile exhibitionism as a hormonal defect? Or the need to rape old women as the effect of conditioning? Or necrophilia as merely a statistic at the outer reaches of a bell curve?

The new research seems aimed unanimously at tearing down the conflict theory; no other aspect of Freud's system has created such resistance, perhaps because Freud believed perversion is *motivated*, i.e., that a person is somehow, in his depths, in part responsible for his perversion. The deviant act, Freud felt, is the product of the great human capacity for choice and so ultimately has a moral quality (even if one's responsibility is mitigated because the choice is unconscious and was arrived at because of unsought threatening circumstances in childhood). The modern researchers, however, deny that intrapsychic conflict plays a part or that fantasy propels and perpetuates deviant activity. In other words, these critics say it is not psychically motivated. Oddly, their same research can apply to nondeviant behavior, for their logic says that *all* sexual behavior is *not* psychically motivated. They believe this in their laboratories and at their desks. Do they also believe it in bed?

ATTACKING CONFLICT THEORY

The attack on conflict theory has taken four forms. The first says that the aberrations in humans are due simply to physiological mechanisms—either organic dysfunction or inherited normal physiology that merely produces behavioral variance of the same type as that seen in lower animals and as the result of the same brain and hormonal mechanisms that are present in lower animals. In the second explanation (learning theory), the deviation is inflicted by an outside force, e.g., conditioning, and so is not a matter of choice and has no origin in fantasy. The third is statistical: there is a bell curve for sexual behavior, and the variations are not abnormal, just not normative. The last says that, while a culture may pronounce a variant pathological, it may only be the social condemnation that is pathological, not the behavior—i.e., the society rather than the individual is sick.

Genetics and Constitution

The following represent the kinds of studies which attempt to demonstrate that sexual aberrations are induced by physical, not mental, forces.

There is much fine animal work (summarized in [33, 34]) since there are now techniques that can be used to influence large areas of the brain by electrical and chemical stimulation or ablation or by the deprivation of REM sleep. These experiments create disruptions in normal sexual patterns in animals, hypersexuality and/or indiscriminate sexual behavior, during which the animal may not care about the sex or sometimes even the species of the object of its attentions. Then there are experiments in which minute amounts of electrical or hormonal stimulation of tiny, circumscribed areas of the brain can change sexual function (35). But our old problem remains: how do *these* neural substrates in animals relate to *that* man's buying photographs of enchained women; why did *that* woman, who was a feminine girl till age six, grow up to be so masculine?

As yet, obviously, no comparable work has been done on humans, though we know that sexual behavior can be changed by manipulation of the brain (32). I have already mentioned a neurosurgical cure of male homosexuality (8). A cure of male homosexuality (36) and treatment of hypersexuality (37) by antiandrogens have been reported. Several reports have tried to implicate the temporal lobes in fetishistic behavior, especially cross-dressing, but these have been either single cases or studies with too few subjects (summarized in Blumer [38]), have lacked adequate controls (39), or have simply been ruminations on research (40). They indicate that a rare case may be associated with temporal lobe disorder, but they do not encourage belief that such brain disorder underlies all such behavior (41). (Why are there no reports of women so affected?)

As to the claims that constitutional predispositions may make certain people susceptible to their particular deviance, there simply is no acceptable evidence as yet, except in the rarest instances (3, 5). No competent studies have shown family tendencies in any of the perversions, except perhaps in homosexuality. The view generally held in the early 1900s—that perversion was the result of "degeneration," meaning some diffuse physical inferiority—has never been backed up by evidence. But all studies, and there are very few, that have tried to demonstrate genetic factors in homosexuality (6, 7) have been unable to withstand the attack of critics so far (42–44).

[6] In addition to this oedipal (interpersonal) theory, Freud felt that specific elements in perverse acts are the result of libidinal fixation. By this he meant that, when the child's further development is blocked by castration anxiety, the boy or girl may fall back upon earlier libidinal gratifications. If, for any reason, the mouth, anus or bowel, urethra, skin, or any other part of the body had been the focus of intense libidinal excitement earlier, the child could regress to this safer and more gratifying "position" in the face of severe anxiety. This accounted, for instance, for anal intercourse among male homosexuals or oral intercourse among male or female homosexuals.

Even Money's observations of fetally androgenized females show that the girls become only mildly masculine in behavior; they are nonetheless heterosexual (3).

It is too soon to say whether this work on genetics and brain function tests psychoanalytic theory (though it could result in treatments that would make psychoanalytic therapy obsolete for some sexual disorders). One must always be cautious (as I was not quite when speculating above about the significance of a pleasure center in the central nervous system) not to equate the discovery of midbrain mechanisms with integrated, motivated human behavior. The limbic substrates for oral and genital behavior lie close together; how many people seriously think that is how man invented oral intercourse? Is the foot center close to the genital center in a foot fetishist? Is masturbation due to activation of a masturbation center in the hypothalamus? I think some of the modern theories were invented by a computer. At the least, it will take a few generations of research on the cortex before we know much about thinking, desire, and behavior; such a cortex does not exist in other species.

Perhaps the greatest recent challenge is found in the reports described above, under Constitutional Bisexuality, which show that the more exclusively homosexual a man, the lower are his testosterone levels and the more defective his spermatogenesis. Such findings, if confirmed, would greatly reduce the importance of a theory that says the condition is caused by disruptions in a boy's relationships with his mother and father. We will have to await further studies that control for such nonspecific influences as stress (45), normal variations in hormone levels during a diurnal cycle, normal variations in semen quantity and content, drug intake (since marijuana may lower plasma testosterone levels), etc. Already there is a nonconfirming study (46).

Learning Theory

Learning theorists are the second group whose research opposes the idea that sexual aberrations are compromise formations serving to salvage sexual pleasure from a situation filled with anxiety and conflict. There does not seem to be a learning theory that attempts, as does psychoanalysis, to account for the development of erotic behavior in humans, behavior that leads either to "normal" heterosexuality or to the aberrations. However, there are studies that suggest we may find roots of sexual behavior that are not the result of intrapsychic conflict.

Imprinting of infant creatures at a critical period can cause attachment to an inanimate object, an animal, or a man, when they would normally be so attached to their mothers. In adult life their choices for mating may then be of the type of the imprinted object (47). While the conceptualizations behind these observations have been extended to the human infant (48–50), no confirmatory data are yet available.

The contribution that classical conditioning makes to the development of sexual behavior has also been investigated. This can be summarized by the belief that, in animals, almost anything is possible in the laboratory: by means of conditioning techniques, an animal can be trained to become sexually aroused by objects that would have no such power in the natural setting; even styles of gratification, such as masturbation, can be artificially produced. How or whether these findings are related to the development of sexuality in free-ranging conditions is unknown.

"Interpersonal" relations as contributory to the development of sexuality have also been investigated in animals. For instance, overcrowding has produced abnormal effects in animals, changing their object choice, styles, frequency, and capability of intercourse (51). Experiments with monkeys raised by abnormal mothers, including inanimate mothers, have caused profound disturbances in socialization and the capacity for reproductive behavior (52). Defects in sexual ability also occur when monkeys are deprived of peer relationships when young (53). These studies seem to justify the stress analysts lay on the influence of interpersonal relationships in early life on later sexuality.

My enthusiasm for many fine animal studies is reduced if the author is unable to resist the temptation, on finding an experiment that produces abnormality, to extrapolate directly to human behavior, even to suggesting modifications in child rearing or in the functioning of whole societies on the basis of his findings in, for example, rats.

Experiments in human conditioning that produce sexual behavior are rare. In one, an easily extinguished mild fetishism was artifically produced by pairing erotically stimulating pictures with shoes (54). Positive and negative reinforcements in a culture may account for changing sexual styles from generation to generation (e.g., women's fashions).

Social learning theorists stress the effects of shaping—reward and punishment—in creating aspects of personality (55, 56), as well as the effects of imitation and identification. Freud and other analysts have also stressed these, as in discussions of the development of the ego and superego (57–60) or core gender identity (5). There are studies on identification in which some learning theorists and psychoanalysts find common ground. These show that the infant-child who spends considerable time in a close and warm relationship with a parent may pick up the gender qualities of that parent. Thus a boy too close to his mother may be feminized but be masculine if he is with his father, and vice versa for girls (5, 18). Analysts disagree with most learning theorists in believing that personality development does not occur without the influence of intrapsychic conflict over affectionate and sexual issues as well.

"Taxonomy"

The third argument is the statistical one, or, to use Kinsey's term, the "taxonomic." (That word was chosen for its implications of objectivity, naturalness, and absence of moral judgement; "normative" is cooler than "normal.") It takes the stance of the naturalist observing humans just as he would another animal species. In Kinsey's hands it became a powerful research tool, though it was just as powerful as a hammer of social morality,

since in this crafty way Kinsey made a judgment by saying we should be nonjudgmental.

His data (61, 62), and the good subsequent sociological work (such as by Gebhard and associates [63]), have not shaken analytic theory, for they demonstrate what analysts had long since known—that human sexual behavior is far more variable than had been admitted. Kinsey's challenge is not in his data but in the positions he took before he even collected any data—that inner life is not pertinent to this psychological research: the observer knows enough when he has finished counting. In that regard, Kinsey is allied with the behaviorists.

Cultural Relativity

The fourth argument extends the third and is exhortative. Here the author uses the research of others to support his position for sexual freedom. This is especially the case with activists banded together to relieve the guilt and social degradation traditionally laid upon them. Homosexuals exemplify this approach, drawing from the first three categories above to deny allegations of abnormality or illness: first, their condition is widespread in lower animals, is inherited, or is hormonally or otherwise physiologically induced; or it is the result of conditioning in childhood and/or adolescence; or it is aberrant only statistically. Crucial for each of these defenses is the relief of guilt: since one's self did not choose it, one is not responsible for it, and besides the condition is not shameful.

There is a great deal of turmoil today (64–68) over whether aberrant behavior is perverse (i.e., nasty or sick) or only deviant (statistically askew); the key words have been "normal" and "healthy." These arguments have been less than inspirational because the contenders, each with Science by his side, have ignored what the opposition meant by "normal" or "healthy." The one group says the perverse person is abnormal because the aberrant behavior can be traced back to childhood trauma and conflict. The other says the deviant is not abnormal because he manages his life, other than his personal preferences, no more peculiarly than heterosexuals, who are not particularly noted in the mass for their happiness and creativity.

For myself, I agree with both—and with neither. I think many aberrations are perversions in the sense that they emerge as solutions to conflicts and thus secrete a burden of guilt and a sense of risk-taking in their core. On the other hand, I do not believe these dynamics cripple most of their owners any more than does the conflict-solving process that produces normative (heterosexual) behavior.[7] We may not solve these moral issues, which masquerade as scientific ones, as easily as each side hopes.

CONCLUSIONS

My task has been to reflect on the impact of the new advances rather than to detail the latter, and so these conclusions can only be opinions.

To sum up, I think the measurable impact on psychoanalytic theory has been mild. First, the theory was drawn up in such a way that most of it cannot be put as propositions to be tested by any scientific procedures yet devised. Second, psychoanalysis concerns man, but the new research does not yet have the techniques to answer its own primary, though usually unstated, goal: to show how the findings of any experiment on animals or on an isolated part of a human subject's physiology or psychic function bear on the sexual behavior of a human in his life as a person, not as a laboratory subject. Still, while the measurable impact on theory has been mild, the impact on analysts may be considerable. Many are listening closely to the researchers; and into the writings and conversations of analysts there is coming an impatience with being confined to theoretical positions that are held together more by tradition than by data.

As in many other areas of psychiatric research, new techniques have led to an upsurge of interest and of findings in the neurophysiological (including chemical) mechanisms involved in many aspects of sexual behavior. Along with this excitement inspired by fine experimentation, there is less enthusiasm than ever for the investigation of sexuality in the human by clinical methods, especially by collecting data in the supportive environment of proper treatment. I think that nothing but good can come from the increased laboratory work and that nothing but bad can come from ignoring the single case studied in depth.

It will be useful if we can reverse the belief that the clinical method is either too weak (as some laboratory scientists are convinced) or has finished its task (as some psychoanalysts tend to feel). Now, years after the work of such observers as Freud, Krafft-Ebing, and H. Ellis, we still need naturalistic observations on sexual behavior, normal and abnormal. The work of Masters and Johnson has convinced us of this. But I am not now referring only to the observation of gross physiological response, which they are doing, but to collecting exact subjective descriptions of the sexual experience, the accompanying fantasies, and the indications of unconscious processes and childhood influences that the psychoanalytic method can collect.

And there may be additional bonuses if we revive clinical research on sexual behavior. For instance, from this neglected area can come great insights into the causes of violence, the current research of which is more to be commended for its volume than for its discoveries. It is no coincidence that violently aggressive people usually have bizarre sexual impulses and severe conflicts about masculinity and femininity. There is a second area that sex research may clarify: some legal and moral issues that turn on questions of responsibility and of normalcy may melt away under the heat of the facts.

Perhaps the group that can give us the most, because they have provided the least so far, is the anthropologists. Their acceptance of sketchy, anecdotal material and their failure to develop a method for gathering detailed, accu-

[7] This is less true as the aberration is more bizarre.

rate material on such a private subject as sexual desire has crippled our understanding of human sexuality. We simply cannot do without their cross-cultural studies, but we also cannot afford the superficial and opinionated reports they have too often given us. Certainly we analysts need their findings to keep us honest, that is, to keep us from generalizing too rapidly from the particular patient we analyze—a member of our culture—to humanity at large.

Finally, I would suggest that we not be jaunty; we still know very little about the mechanisms or causes of human sexual behavior, normative and variant, normal and abnormal. We still know too little about what effects the unfolding of sexuality after the essential inputs of heredity, constitution, and early environment. We know too little even about what people do, what they think they are doing, what they think while they are doing it, and what they think of what they are doing. However, I hope I am not too optimistic in saying that we are now developing, for the first time, tools and ideas that will enable us to study these issues well.

NEW SUBSCRIPTION RATES FOR THE JOURNAL

To keep pace with rising production costs, the Association has found it necessary to increase the price of subscriptions to *The American Journal of Psychiatry*. Starting with the January 1973 issue, the price was raised to: U.S., $15; Canada and South America, $15.75; other foreign, $18. A single copy now costs $1.75 plus postage.

Motivation for Medicine in the Seventies

BY JOHN F. MCDERMOTT, JR., M.D., WALTER F. CHAR, M.D., AND MARGARET J. HANSEN, M.S.W.

A department of psychiatry in Hawaii undertook an exploratory study of the motivational patterns of entering freshmen, relating these to problems of selection, performance, and the educational system itself. The authors, noting that the motivations of students seem to be changing and that a different value system is emerging, call for further study to more accurately assess the values and needs of prospective students and to reassess the educational process.

WE ARE NOW in the era of redefining the objectives of medical education and of redesigning curricula on the basis of these new objectives. These changing directions have vast implications for the selection of medical students. This paper is an attempt to sort out some factors that are important in the process of selection of medical students within the context of changing medical objectives.

In the past, it has generally been felt that the Medical College Admission Test (MCAT) and premedical grade-point average (GPA), if used as principal criteria for selection, would identify the smart, achievement-oriented individuals who know how to get good grades (1) and would be successful in medical school. Recently, however, educators have been questioning more and more the correlation between scientific ability and clinical competence in the practice of medicine. It is increasingly observed that the entry profile of the medical student is heavily biased toward scientific achievement in college and performance on the MCAT. These measures are probably relevant in predicting achievement in the first two years of medical school, when basic sciences are emphasized, but are probably less valid as criteria for clinical competence. For example, it is now generally agreed that the MCAT, "with its limited objective to predict successful academic performance in the basic science segment of the medical school curriculum" (2) should be made more responsive to current needs.

There have been many attempts to consider other factors since the 1950s, when studies focused on the medical student and the fundamental process of becoming a physician (3, 4). Lief and associates (5) and Menninger (6) presented psychological profiles of students (predominantly obsessive-compulsive) and hypotheses of various unconscious motivations for medicine as a profession (healing instead of hurting, curiosity, mothering, etc.). A number of studies attempted to assess a personality factor in the selection of medical students; the MMPI was the most commonly employed measure (7). These and other studies produced findings that were conflicting when the student's progress was followed. Some researchers believed that the best students were more sensitive and idealistic (8), others that the best students were more aggressive and ambitious (9)—that successful students were influenced more by a desire for independence and prestige than unsuccessful students, who were more influenced by religious and service motivations. Personal motivational factors *are* likely to be crucial determinants for predicting clinical competence, but they, like competence itself, are very elusive and cannot be measured satisfactorily; this may account for the overuse of factors that can be quantified.

Recent innovative efforts to examine selection criteria seem more promising than those of past decades. The admissions committee at McMaster University Medical Center in Ontario, Canada, for example, has developed a complex selection procedure that includes the evaluation of student essays to assess personal motivational factors such as: motivation and goals; attitudes toward the McMaster M.D. program; response to intellectual, personal, and social problems; personal relationships; and self-appraisal (10).

The present study, conducted at the University of Hawaii School of Medicine, is an attempt to further refine our understanding of social motivations in medical students in the 70s and to explore the significance of these motivations for medical education and the practice of medicine. The implications are important, for this is an era when the role of medicine and of the doctor is in transition, reflecting changing social structures, values, and needs. More physicians now need to be trained more rapidly and to be prepared for new models of community practice. The doctor of the 70s will be required to be more flexible and versatile, to be able to collaborate, and to inspire a broader basis of community participation in medical care delivery than physicians in the past. On the surface, at least, these requirements seem in conflict with traditional medical student motivational patterns related to intellectual mastery, autonomy, independence, competitiveness, and aloofness. Medical educators are recognizing that there is a potential for increasing conflict between the changing needs of medical practice (which

The authors are all with the Department of Psychiatry, University of Hawaii School of Medicine, 3675 Kilauea Ave., Honolulu, Hawaii 96816, where Dr. McDermott is Professor and Chairman, Dr. Char is Professor, and Ms. Hansen is Assistant Professor.

medical education must meet) and the traditional selection process of medical students.

METHOD

At the University of Hawaii School of Medicine, the Department of Psychiatry has undertaken an exploratory study to examine the motivational patterns of entering freshmen and to relate these to the problems of selection, performance, and the educational system itself. The initial phase of this project involved a request to each freshman entering in 1970 to write a personalized essay about why and how he decided to enter medicine. The essays were examined for patterns of motivation, with consideration given to sociocultural factors that are important in studying our multiracial student body.

Next, the top ten and bottom ten students (the latter expanded to 16 because of identical grade-point averages for tenth place among seven students) were compared as to the form and content of their essays at the end of their freshman year.

The limitations of this study are well recognized. Our analysis of the essays is highly subjective and impressionistic. Lack of a statistically controlled sample, as well as the difficulty in measuring essay content and the weakness of using only grade-point averages at the end of the first year as a criterion of adaptation, are to be questioned. However, the special advantages of this population for such a study—their lower socioeconomic status and racial mix[1]—should also be recognized. The multiracial, lower socioeconomic class students who participated in this study may, in fact, accurately reflect the motivational characteristics of future students, for the trend is to broaden the socioeconomic, cultural, and ethnic base from which medical students are selected.

Thus our results and discussion of them serve mainly to raise questions and to point to directions for further study. We hope eventually to define criteria leading to the development of a motivational measurement profile that will be useful to the students, the school, and the community. In addition, we hope to raise questions about the reciprocal relationship between selection and the educational system itself.

RESULTS

All students gave more than one reason for entering medical school; the motivational patterns appeared to fall within three broad categories:

Personal Motivations

This category has traditionally been considered the principal one among medical students and implies certain personality characteristics. Our students described entering medical school as part of their striving for independence, social status, respect, acceptance, recognition, financial security, and personal stimulation. The need for autonomy was stressed as a motive; one student expressed it this way:

> In retrospect, I would say that the greatest appeal for me in medicine [is] the opportunity to work independently. I think my desire to work independently has very deep natural roots. One of the most powerful urges in man is ownership, and I wish to have a profession in which the end product is something which I can largely call my own work.

Medical school and medicine were seen as an experience that would provide opportunities for competition, recognition, and self-assurance—described by one student in this manner:

> Throughout school, I always wanted to be number one. I wanted to read the fastest, to make the best grades, and to outdo everyone simply for an enjoyable distinction. . . . I always ended up with the leading part in plays, I starred at sports, and even did well flipping bubble gum cards.

Personal Factors Related to Family and Ethnic Motivations

This category, while also a traditional one, undoubtedly has special significance and emphasis in our population. Students cited many examples of experiences within their families that motivated them to enter medical school. Many students described the sacrifices they had seen their parents make in order to provide for them and send them to school; they felt that becoming a medical doctor would be a means of repaying that debt. This was particularly true of the large Oriental group of students found in Hawaii. Other students described feeling pressured by family expectations or by competition with siblings for achievement. Hawaiian students wanted to disprove what they felt was a stereotype of laziness.

Critical experiences having to do with illnesses and deaths occurring in their families seemed also to be decisive factors in many students' decisions to enter medicine.

Many of the students presented material in their essays to indicate that they had unresolved conflicts with their parents that were related to their motivations for entering medical school. Such conflict was described this way by one student:

> My father . . . was brought up in the old tradition which taught that a father must be strong but, for the most part, silent. . . . The tradition of silence meant that he had very little contact with the four of us. He never concerned himself with the affairs of his children.
>
> Obviously, I did not feel loved at home, so I was forced to find it [love] among my friends at school. . . . I gained respect from my friends on the basis of my achievements in school. . . . Becoming a physician [is] a compensation for my feelings of inadequacy, a means to gain respect from the community and my friends.

Social Motivations

This category, often previously called "service" and

[1] In a previous study at the medical school of the University of Hawaii it was found that two-thirds of the students chose this school because of financial considerations; one-half of the students in the class came from families with an annual income of less than $10,000.

associated with poorer students than with those who were primarily status-oriented, was the most prominent and significant one among our students of the 70s. It seems to be qualitatively different as well. Of course, some of the social concerns were stated rather simply—wanting to help the weak, the sick, and the poor, to relieve human suffering, and to combat death. Some described religious backgrounds that were related to their vocational choice and combined their broad social and religious idealism with a specific personal identification with such figures as Tom Dooley, Albert Schweitzer, and Robert Kennedy.

It was particularly noted, however, that the majority of the students expressed their social concerns in a complex, realistic manner, reflecting a deep personal involvement with the issues and concerns of the 60s and 70s.

The conflict in Viet Nam was mentioned repeatedly as a social issue that had affected the lives and aspirations of the students. One student who had actually been in Viet Nam stated it this way:

> In retrospect, this experience had more impact on my attitudes than any other single experience, in that it provided the impetus for active pursuit of a medical education.... Unimaginable poverty was a real and daily sight in many areas visited. In Viet Nam, the effect of war on a generation of people was tragic. In this environment, medical doctors were critically needed. The work of physicians and corpsmen in providing even elementary medical aid to these people was quite impressive. It was felt that these medical personnel were really engaged in a rewarding occupation and I wanted to become a part of it.

Almost all the students wrote directly or indirectly of going into medicine as a way of self-actualization, of finding a more holistic approach to life in an existential sense, and of experiencing personal interrelationships with others. One student wrote:

> The patient-physician relationship has emotional components that transcend the physical reality of what the relationship accomplishes. I find it difficult to express, but there is something about this that is outside of time and place. Such concepts as friend or love are similar in that the true reality of the concept is not limited physically. The physician becomes a part of the patient's life and the patient reciprocates. It is a basic, primary relationship and probably has identifiable components that are similar in all cultures, perhaps in all times. There is a mysticism, a sharing, that is basic to the relationship which appeals strongly to the emotional part of my nature. This sharing of sickness and the attempts to alleviate it give meaning to the doctor's life in a way unique to medicine.

In discussing their social motivations, many of the students indicated their understanding of the potential for conflict in their choice of medicine as a career. They could already feel the basic contradiction between those forces motivating them to compete, to acquire financial security and status, and those forces which motivate them to be involved in the social-relationship issues that concern young people today.

One student expressed it this way:

> I fear what I am becoming, as I am beginning to contemplate the money I can make, the desire to specialize and escape the small town which was the original reason I wanted to enter medicine. I am beginning to feel the draw of power and status.... I am beginning to have a lack of enthusiasm for learning, and have begun to feel that I will never again be free and able to relax, to really be a father and husband, to be my own self, to do what I want to do.

Further Analysis of Essays

In an attempt to extend the analysis of the essays further, the best students were compared with the poorest students by grade-point average at the end of the first year of medical school.[2]

The most significant finding seemed related to the strong element of personal and family conflict in motivation for medical school, which was found equally and almost universally in both groups but was expressed in different ways. Among the students with the lowest grades there appeared to be a markedly less logical and smooth progression toward medicine. They backed into medicine because it was the most practical thing to do, or medicine appeared to be an inspirational mission in which the students seemed overly involved with personal and family pressures to prove themselves worthy. The students with the best grades also manifested conflicting motivational patterns, but they were more logical and better organized in their presentation of life's experiences and events. They seemed more independent in detaching themselves from the anxieties in their lives and did not continue to reiterate them. Their social idealism seemed tempered with scientific interest and experience in dealing with people.

It appeared that many of both the top and the bottom students in the class had not come directly to medicine but had spent time going in other directions and exploring other vocational opportunities. Neither group had more time than the other to work out the conflicts that appeared so prominently in their lives, but the best students showed an organized and integrated approach to their choice of medical school, suggesting that entering medicine was a final phase of a resolution rather than another symptom of conflict.[3]

[2] Correlating the students' academic achievement in their first year with their entering GPA and MCAT scores revealed that in the top ten students six had higher and four had lower MCAT scores than the class average (548); comparing their GPA scores, six scored higher and four scored lower than the class average (3.04). Only one, however, was below his class average in both his GPA and MCAT scores.

Of the lower 16 students, 12 had lower and four had higher MCAT scores than the class average; again 12 had lower and four had higher GPA scores than the class average. Here nine students were below class average in both the MCAT and GPA scores.

Thus, our preliminary studies do seem to indicate that the traditional reliance on MCAT and GPA scores in medical education has some merit for the first year at least. (This is especially true if the MCAT and GPA scores are used jointly.) But they seemed to be a better prognosticator of academic failure than of academic success.

[3] This, of course, is not surprising; it is consistent with impressions of medical students made by others. Utilization of the human figure drawing in predicting academic failure or success (11) has suggested that the relatively unsuccessful students were more likely to produce drawings that were poorly organized, faintly sketched, and lacking in detail and in a systematic approach to the task; the more successful students produced drawings that showed better overall organization and appropriate detailing and that gave the impression of a higher energy level.

DISCUSSION: SOME IMPLICATIONS

Several of the findings, although tentative, seem relevant to current issues in medical education. The medical students who participated in this study seemed to have broader motivational patterns than did students in previous decades. They evidenced the expected personal and family motivations. However, what was called "service" motivation in the past (11), sometimes identified as characteristic of the poorer student, seems to have changed qualitatively and quantitatively. It is seen as a primary and powerful personal part of the identity formation of the young student physician of the 70s. The students seemed to be highly conscious of contemporary social issues and concerns and to have directly related them to their choice of medicine as a career. However, this strong social relatedness also seemed to produce conflict with other motivational forces, such as motivation for status, financial security, and independence, and also possible conflict between their self-definition and the rigorous demands made of the medical student and physician as defined by medical educators in the process of medical education. Some degree of conflict as to motivation was observed in all of the essays, but the approach to the handling of the conflict by the individual student seemed to be the crucial factor in his ultimate success.

Implications for the selection and recruitment process are important. With the need for many more physicians with different styles of functioning and with an increasing emphasis on clinical competence it is essential to more accurately define and measure clinical competence and to assess and predict which motivational factors are associated with this most important quality and end product of medical education. A profile of minimal basic traditional ingredients, such as seriousness of scientific purpose, conscientiousness, thoroughness, etc., should not be thought of as the only or complete profile or extended to embrace associated compulsive character traits as an ideal. Rather, these traditional motivations need to be combined with social motivation; i.e., the *kinds* of motivation and their integration become more important in student assessment today than the intensity and single-mindedness of the motivation. Perhaps a method of measuring these behavioral factors and the capacity for conflict resolution can be designed on the basis of further study of motivational patterns and can be weighted in the student's entry profile. This behavioral profile, together with the traditional MCAT and GPA scores and the pre-admission interview, would give a more complex and comprehensive view of the prospective student and, one hopes, would point the way toward the recruitment and selection of the kind of student with broader qualifications and capacities who may not be entering medicine at present.[4]

Finally, the findings of this study have implications not only for medical school admission policies, but also for the process of educating students once they have been admitted, for the process of medical education produces stresses on the student that change him and his values and affects the resolutions of his conflicts either favorably or unfavorably. Perhaps an effort should be made to reconsider the stresses of medical school, to make medical education more continuous with other total life and social issues (as is being done through the introduction of early clinical experience), and to encourage student-developed programs for the medically underserved.

Within this context many pertinent questions can be raised. Can medical educators build some solutions into the educational process itself, in order to enable students to deal with increasing conflicts around value systems, identity crises, and interpersonal problems as they struggle to cope with the increasing complexities of the role and function of medicine? Can improved, more easily accessible counseling facilities be provided to assist the student with such crucial problems as the effect of the demands of medical school on marital and family relationships and the critical choice of a medical specialty? What of the issue of the length of medical school education? Does the trend toward shortening medical school and abolishing internships shorten the time medical students need to mature and resolve conflicts in order to establish themselves securely in the role of physician?

Today's students seem to value an awareness of others' needs and collaboration as much as previous generations valued individual, competitive achievement and success. It therefore becomes understandable that they favor a pass-fail grading system and find the curved GPA in direct conflict with their motivations and the qualities they feel are needed in the future physician.

One thing seems clear. If the motivations of students are changing and a different value system is entering with the new students, a seriously disruptive generation gap will exist unless the faculty and the educational system recognize these changes and adjust to them. To admit new kinds of students into the same system that rewards only the older, narrow kind of student profile is dangerous and self-defeating. Further study is needed to enable us to more accurately assess the changing values, motives, and needs of prospective students and to reassess the educational process and the significant ways in which it shapes the future practitioner.

[4] The McMaster University Medical Center Admissions Committee has instituted as a pilot project a group problem-solving process by which five or six applicants are given a task or problem to work on; they are assessed according to how they interact with each other and to their ability to express their ideas and to tackle the solving of a problem. Tentative data suggest that this problem-solving situation gives an assessment which correlates very closely with the assessment done by three interviewers interviewing a single applicant.

FORTHCOMING SPECIAL SECTIONS

The April issue of *The American Journal of Psychiatry* will include a Special Section on suicide. That issue will also contain an article by Lloyd J. Thompson, M.D., of Chapel Hill, N.C., titled "Learning Disabilities: An Overview."

The Special Section in the May issue of the *Journal* will be concerned with undergraduate medical education.

Emergency Room Treatment of the Drug-Abusing Patient

BY JAMES L. CHAPEL, M.D.

The author outlines the preferred treatment of patients appearing for emergency care with acute symptoms suggesting drug overdose or a "bad trip." He discusses symptoms and treatment of patients who have abused heroin, "downers," alcohol, stimulants, cocaine, hallucinogens, marijuana, or belladonna derivatives.

METHODS FOR TREATMENT of the acutely reacting drug abuser appear to be inconsistent and widely diverse. Furthermore, and much more important, a majority of practicing physicians admit their lack of knowledge on how to deal with this problem. Discussions with residents (both medical and psychiatric) who are responsible for emergency room services reveal that their management of these cases is dictated largely by their intuition or by "lapel holding consultation" with the few staff physicians who have had experience with this type of patient. It would thus seem appropriate to present a brief outline as a point from which to begin when a physician is faced with a drug abuser with an overdose (OD) or a "bad trip."

I will deal only with the more commonly abused drugs and will begin by describing general procedures applicable to all unconscious patients to be considered here.

GENERAL GUIDELINES: UNCONSCIOUS PATIENTS

Respiratory adequacy must be ensured immediately, since this is usually the most important single factor in determining life or death for the patient. The airway should be cleaned and the physician should breathe for the patient if he is unable to do so himself.

The vital signs must be attended to and recorded as indicated: level of consciousness, deep tendon reflexes, pupil size and reactivity, blood pressure and pulse rate, and respiration.

Intravenous administration of a solution of five percent dextrose in water should be started; the blood drawn at that time should be saved for study of drug levels.

Urinalysis should be done as soon as possible.

It is important that the family or friends who brought the patient to the emergency room be asked to remain and give pertinent information. Samples of the drug that the patient may have taken should be requested for laboratory assay, since few of the drugs are pure. Personal information such as life-style, preference for certain drugs, dosage usually taken, etc., should be requested. The physician should also ask about the presence of physical conditions that may mimic a drug reaction (diabetes, seisure disorder, hysteria, etc.) or complicate the primary problem. Assume and be concerned about the possibility of multiple drug use and of the coexistence of alcohol.

TREATMENT OF CERTAIN DRUG OVERDOSES

Heroin

The unconscious patient. The overdose may be due to a willful intentional overdose ("hot shot"), or it may be accidental.

Signs and symptoms include apnea or slow respirations (2–6 per minute); cyanosis; absent reflexes; pulse varying from strong to weak, depending upon the degree and duration of hypoxia; small pupils; and urine testing positive for opiates. If the overdose is severe, pulmonary edema and/or respiratory arrest may result. If the patient is in pulmonary edema, he should be treated in the orthopneic position and given a diuretic, e.g., 20–40 mg. of furosemide (Lasix) intravenously in one to two minutes. Digitalization should be considered, as well as intubation or tracheostomy, plus continuous positive pressure ventilation with an oxygen concentration of at least 40 percent.

Specific treatment consists of administering one of the narcotic antagonists: levallorphan tartrate (Lorfan), nalorphene (Nalline), or naloxone hydrochloride (Narcan). These counteract or prevent excessive respiratory depression resulting from the use of heroin, morphine, or other drugs with a morphine-like effect (e.g., hydromorphone [Dilaudid], methadone, leritine, alphaprodine [Nisentile], and meperidine [Demerol]). Administration of an antagonist to a patient with severe respiratory depression due to these drugs usually causes a prompt increase in the respiratory rate and minute volume. If opiates are *not* the cause of the coma, then the antagonists themselves act as opiates and may cause respiratory depression with repeated doses. Especially is this true with a patient who already has depressed respiration, as in barbiturate poisoning.

The dosage of levallorphan tartrate is 1 mg. administered intravenously; the dosage of nalorphene is 10 mg. administered intravenously. The dose may be repeated at 10–15 minute intervals if necessary, but no more than three doses should be given.

Naloxone hydrochloride (Narcan), a new antagonist,

Dr. Chapel is Professor and Chief, Section of Child Psychiatry, University of Missouri College of Medicine, 803 Stadium Rd., Columbia, Mo. 65201.

The author wishes to thank his colleagues Charles Mengel, M.D., and Garf Thomas, M.S., for their help in reviewing this paper.

does not depress respiration. The dosage is 0.4 mg. administered intravenously or intramuscularly in adults; this can be repeated as needed without danger.

If veins are "burned out," one should inject into the base of the tongue or the jugular vein.

It is important to note that if the overdose is due to methadone, breathing should be monitored for 24 hours because toxicity may last up to 24 hours, while the antagonists are effective for only two to four hours.

"Downers"

These include barbiturates and nonbarbituric sedative-hypnotics and anti-anxiety agents such as diazepam (Valium) and chlordiazepoxide (Librium).

The unconscious patient. Signs and symptoms include shallow respirations (may be slow or rapid); circulatory collapse; cold, clammy skin; cyanosis; constricted and nonreacting pupils; hyporeflexia or areflexia; and possibly pulmonary edema.

Treatment includes hospitalization and use of general guidelines (see previously) for the unconscious patient. Gastric lavage may be dangerous in any comatose patient because of the possibility of aspiration pneumonia. An endotracheal tube with cuff should be inserted under direct vision before a gastric lavage is begun. Hyperthermia and cardiac arrhythmias are also dangers.

There is no true antidote for barbiturates. The artificial kidney or peritoneal dialysis may be indicated in severe cases, but ventilation and fluid management will usually suffice.

The clinical picture of intoxication from anti-anxiety agents resembles that of barbiturates; management is the same (1).

The conscious patient. Signs and symptoms include a "drunk" state; respiratory depression in which the depth is affected but not necessarily the rate; incoordination-ataxia; drowsiness; smaller pupils than normal; mental confusion and disorientation; slurring of speech; headache; and nystagmus.

There may be euphoria, irritability, or excitement. Moderate or severe poisoning may cause delirium or stupor.

In regard to treatment, if the patient is responsive, drugs should not be given. If he can swallow and has ingested the drugs, 30 cc. syrup of ipecac or 2–3 teaspoonsful of powdered mustard in water should be given to promote vomiting. Supportive care should be continued in the hospital. The condition usually clears in one to two days.

Alcohol

Alcoholic hallucinosis. This may be short-lasting or may go on for weeks. The hallmark is auditory hallucinations. The patient is distrustful and has ideas of persecution and reference, but he is oriented as to time, place, and person.

Hospitalization is preferable.

Phenothiazines are indicated in the management: e.g., 200 mg. of chlorpromazine twice a day by mouth; this may be increased if necessary.

Acute alcoholic excitement. Some people develop acute psychotic reactions from alcohol, resulting in great excitement and combativeness, with or without hallucinations. This is usually a brief, self-limiting condition but can result in coma and death.

Treatment includes initial administration of 200 mg. of chlorpromazine by mouth and 50 mg. repeated every hour until the excitement starts to subside. Or 10 cc. of paraldehyde may be given by mouth every two to four hours until symptoms subside.

Alcoholic DTs. These are seen in chronic alcoholics during withdrawal or after heavy bouts of drinking; they can occur from one day to one week after the last drink.

Signs and symptoms include disorientation, fear, visual and sometimes auditory hallucinations, tremors, tachycardia, and sweating. There may ultimately be peripheral vascular collapse.

The condition lasts three to seven days and is sometimes fatal. During DTs the patient may be overactive, restless, and excited. He may try to escape from his hallucinations and may be suicidal. He can be very suspicious, aggressive, and unpredictable.

For treatment the patient must be hospitalized. Fluid balance is critical; most patients will require several liters a day. Paraldehyde should be given by mouth or intramuscularly every hour until sleep occurs and then every four to six hours. Or 100 mg. of chlorpromazine may be given intramuscularly every two to four hours. Diphenylhydantoin (Dilantin), 100 mg. every four hours, may be added to prevent convulsions.

Stimulants (Amphetamines, Methamphetamines, etc.)

Signs and symptoms include aggressive, explosive, paranoidal, and violent behavior; poor nutritional state if the patient is a chronic user; racing thoughts; such other symptoms as tremor, dry mouth, tachycardia, sweating, hyperthermia, hyperreflexes, lability, anxiety, tension, aggressiveness, and "crankbugs" (the sensation that "bugs" are crawling under the skin). There may be an elevation of blood pressure and there may be convulsions. (Chronic amphetamine use often leads to heroin use as a "downer.")

In regard to treatment, if the patient is very agitated and aggressive he should be sedated with 100 mg. of secobarbital (Seconal) by mouth, repeated every 30 to 40 minutes. Blood pressure should be checked. When the "high" starts to come down, the secobarbital should be stopped.

As an alternative, 50 mg. of chlordiazepoxide may be given intramuscularly, followed by 25 mg. orally every hour until the patient quiets down, or 20 mg. of diazepam by mouth, immediately followed by 10 mg. every hour until the patient responds.

Cocaine

Signs and symptoms include gregarious, hyperactive behavior, tachycardia, loss of appetite, racing thoughts, and euphoria. There may be crankbugs and/or twitching. Treatment should be sedation, if necessary, as in the case of patients suffering from an overdose of stimulants.

Hallucinogens

Those seen will be the small percentage who are having "bad trips." Overdose to the point of unconsciousness is probably unknown. In most instances the patient may report that he has had only one drug but it is more likely that he has had a mixture of STP, LSD, stimulants, cocaine, and even heroin.

LSD, mescaline, peyote, etc. Symptoms may include panic, anxiety, fear, depression, loss of control, or depersonalization.

The safest method of treating this type of emergency is "talking down." If the physician cannot do this himself, help should be requested from one or more experienced drug abusers in the community. If such help is not available, 500 mg. of chloral hydrate should be administered; it should be repeated in one hour. Or 20 mg. of diazepam may be given by mouth, followed by 10 mg. as needed.

Short-acting barbiturates such as secobarbital may be indicated at times in addition to, or instead of, chloral hydrate or diazepam. The patient should be removed to a quiet, well-lighted room and kept under observation. He should *not* be left unattended.

Assurance should be offered, and the patient should not be chastised, scolded, or argued with. It should be noted that no deaths directly caused by LSD overdose in an adolescent or adult have been recorded.

STP. "Bum trips" are more common with STP than with LSD; the patient is more anxious or panicky because of the stimulant-like effects of this amphetamine congener. The signs and symptoms include a high pulse rate, palpitations, and sweating. The patient may think he is having a heart attack. The treatment is the same as for LSD. Phenothiazines should be avoided.

Marijuana

Overdoses of marijuana or hashish are rare. If one sees this type of patient one should suspect an underlying emotional illness. Common symptoms of marijuana use are red eyes, increased pulse rate, and dry throat. Fear, panic, and agitation will be the chief reasons for the patient's appearing at the emergency room. There may be paranoidal thinking and feelings of depersonalization in the chronic abuser.

The treatment is the same as for hallucinogens; i.e., "talking down" is the treatment of choice. It is reported that a marijuana high may be ended by increasing the heat of the skin: e.g., through the administration of 100–200 mg. of nicotinic acid by mouth, a hot shower, or ingesting Mexican hot pepper (2).

Nausea and vomiting may occur from the ingestion of brownies or other sweets containing marijuana. Treatment for this, if considered necessary, is 1/150 gr. of atropine administered intramuscularly. It should be noted that no deaths have been reported from marijuana use.

Belladonna Derivatives

Atropine, scopolamine, etc., contained in such nonprescription drugs as Asthmador, Sominex, Sleep-tite, San-man, Mr. Sleep, and Contac are responsible for these reactions. The signs and symptoms include fixed, dilated pupils; dry mouth and skin; ataxia; mild tachycardia; hallucinations; toxic delirium (as in DTs) with amnesia after the "jag"; and hyperthermia.

Treatment should start with gastric lavage if the material was ingested recently (the tube should be well lubricated) or administration of an emetic (2–3 teaspoons of dry mustard in water).

One hundred mg. of sodium pentobarbital (Nembutal) should be given orally or intravenously (slowly) to a maximum of 300–500 mg. Or 10 cc. of parahydrahyde may be given orally and repeated every hour as needed; another alternative is 0.1 gm. of secobarbital by mouth as needed. Phenothiazines should not be used. Physostigmine salicylate, 2 mg. given intravenously or intramuscularly, has been recommended (3). The dose can be repeated in 15 minutes if necessary and at intervals of one-half to two hours if necessary.

General Precautions

A thorough physical examination should always be performed and such physical conditions as insulin shock, meningitis, subdural hematoma, and stroke should be ruled out. The physician should look for "tracks" (needle marks).

One should be aware that many drug users use multiple drugs at the same time.

The average hallucinogenic drug user does not become psychotic under the influence of the hallucinogen. If he does become psychotic, an underlying serious emotional problem should be suspected.

All acutely reacting drug patients should be kept in a quiet place. They should not be left alone. "Speed" (amphetamine) is dangerous. Users often are violent, explosive, and unpredictable. Users of barbiturates are also said to be dangerous and explosive.

Withdrawing alcoholics may seem alert and cooperative but may go on to develop DTs and become suicidal one to six days after withdrawal from alcohol. Patients with uncomplicated DTs have a ten percent mortality rate; if there are medical or surgical problems the mortality rate may be as high as 25 to 40 percent.

For a more detailed discussion of treatment of acute drug intoxications, see Koumans (4).

Patterns of Drug Abuse Among Military Inductees

BY JOHN P. CALLAN, M.D., AND CARROLL D. PATTERSON, M.D.

A questionnaire concerning drug abuse was administered to 19,948 new military inductees over a six-month period. Almost one-third of the subjects had used drugs, but most were casual users. Marijuana and hashish were most frequently used. There were higher rates of use among college dropouts and men from unstable families, urban areas, and families with high incomes. There was little racial difference in overall drug use. However, nonwhites used amphetamines, barbiturates, and heroin twice as much as whites, while whites tended to use marijuana, hashish, and hallucinogens.

NOT TOO MANY years ago, reports to the general public concerning the abuse of drugs ranged from personally prejudiced views reflecting "no problem" to the alarmist's opinion that "Everyone's doing it." There were few scientific studies of the incidence of drug abuse. Soon, some civilian population "chemical Kinsey" reports appeared to help replace biased opinions with more objective evidence regarding the nature of the drug abuse problem in the United States. However, many of these earlier studies were concerned with drug abuse in college and university communities, which admittedly were a small segment of a larger potential, and perhaps actual, population of drug users in America.

Moreover, many of these earlier surveys were limited not only in terms of sample groups, but also with respect to geographical sampling, since most were done in the northeastern (1–5) and western United States (6, 7), areas insufficient to yield good evidence for generalization about drug abuse in other parts of the country.

Only more recently have surveys been conducted among groups in the southern (8) and Rocky Mountain (9) areas of the country. Yet even these later studies, particularly that in Dallas, Tex. (8), may not be comparable to surveys done in the eastern United States due to the different populations sampled, i.e., college students versus junior and senior high school students. With the exception of a military survey conducted in Oklahoma (10), there have been no large-scale surveys published of drug abuse patterns in civilian or military populations in the midwestern and central plains areas of the United States.

Like their civilian counterparts a few years ago, the military is now investigating the drug abuse patterns of its members. There appear to be a number of recent studies of the incidence of drug abuse in the Army (11), although few have thus far been published. In 1969, Black, Owens, and Wolff (10) surveyed a heterogeneous group of 5,482 active-duty men, including trainees, stockade prisoners, and men returning from overseas duty. All had been in the Army a minimum of two months. The researchers found that 27 percent of the sample had used LSD, amphetamines, heroin, and marijuana; however, the inclusion of 434 stockade prisoners may have caused the percentage of drug users to be spuriously high.

Many civilian and military studies either restrict their investigation to only a few parameters or are subject to criticism of their methodology. Some (1, 2, 4) have used a mailed anonymous or coded questionnaire, with a return rate of 55 to 80 percent. This introduces a potential bias in that the nonresponders may have been users and did not wish to risk disclosure. Other studies have limited their drug abuse questioning to a particular race (12, 13), have been concerned with only one to three drugs (7, 9, 14), or have included drugs such as paregoric and nonprescription cold and cough medicines, all of which may normally be used by the population surveyed (8).

In addition to the concern for sample population age, type, and geographical location, another factor of importance in drug abuse surveys is time. As a result of sometimes rapidly changing attitudes and practices, the incidence of drug abuse can fluctuate, with some drugs enjoying more "popularity" at one period than at another. Drug abuse seemed to accelerate in the mid 1960s and perhaps leveled off in 1969 (5). Surveys need to be periodically repeated in order to get up-to-date figures; as of January 1971, there had been no known publication of the results of large-scale drug abuse surveys conducted after 1969.

With all of the foregoing in mind and with a need to assess the magnitude of the drug abuse problem "inherited" by the military from the civilian population (the military often being maligned as causing or increasing drug abuse in young men), the following study was done.

SUBJECTS

We realized that a drug abuse problem existed in the military, but were unaware of its magnitude and how, or

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Callan is Director, Psychiatric Clinic, St. Francis Hospital, 114 Woodland St., Hartford, Conn. 06105, and Dr. Patterson is Assistant Professor of Psychiatry, Missouri Institute of Psychiatry, University of Missouri-Columbia School of Medicine, St. Louis, Mo.

if, the military experience changed the abuse pattern. As a first step we gathered drug abuse data from individuals by means of an anonymous questionnaire given to every new male inductee at a large Army training center in the midwestern United States from January 15, 1971, through June 30, 1971. Although these men were in the Army, they had been in for less than two days, so their responses essentially pertained to their experiences with drug abuse prior to their entrance into the military.

Most of those surveyed came from the midwestern United States. Ninety-eight percent came from induction centers in St. Louis, Mo., Omaha, Neb., Minneapolis, Minn., and Houston, Tex., as well as from centers in Ohio, Oklahoma, Tennessee, and Wisconsin. About two percent came from induction centers in Los Angeles, Calif., Chicago, Ill., San Antonio, Tex., and Little Rock, Ark.

METHOD

The questionnaire consisted of 20 separate questions.[1] The first ten dealt with demographic data—age, race, education, religious practices, marital status, military component (e.g., drafted, enlisted, etc.), family stability and income, and size of home community. The next five questions asked whether any drugs of abuse had been used and, if so, the methods of getting and using them.

The next question, number 16, was concerned with 14 chemicals that might have been used and included data about age at onset of use, number of times used, method of taking drug, and amount of time since last use of each drug. The drugs, listed primarily in alphabetical order, included amphetamines, barbiturates, cocaine, DMT, heroin, hashish, LSD, marijuana, mescaline, morphine, opium, psilocybin, and STP, as well as glue. Because these chemicals might not be known to some individuals by their questionnaire names, a sheet was given to everyone that listed many synonyms and "street names" for each drug on the questionnaire.

Question 17 asked for a "yes" or "no" answer as to whether the person had used a drug not listed on the questionnaire. Question 20 asked if the person had ever had an undesirable or unpleasant effect from drug abuse. Space was provided on the back of the answer sheet for elaboration on "yes" answers to questions 17 and 20.

Question 18 required a "yes" or "no" answer as to whether the person planned to continue to use drugs. Question 19 listed a choice of 12 possible reasons why he had first used a drug.

Testing was done five days a week in groups of 50 to 300 in two adjacent buildings specially designed for testing incoming new military personnel. Except for the fifth month of testing, each man had an individual booth with a desk separated on three sides by partitions high enough to ensure privacy. Due to administrative problems, the fifth month of testing was done with the subjects filling out the forms in open pews.

[1] Copies of the questionnaire are available from the authors.

TABLE 1
Prevalence of Drug Use

Drug Used	Total Number of Users*	Percentage of Total Population** (N=19,948)	Percentage of Drug Users** (N=6,203)

*Numbers total more than total population because of multiple-drug users.
**Percentages total more than 100 percent because of multiple-drug users.

Groups were instructed on the testing procedure by a representative of the post Mental Hygiene Consultation Service, who clearly identified himself as such. It was stressed both verbally and in writing (on the questionnaire) that the subjects were participating in a confidential research study and that their answers would not affect their Army assignment in any way. Emphasis was also placed on the anonymity required, and it was made clear that no identifying marks were to be made on the answer sheet.

By use of a prerecorded tape fed through loudspeakers, each question was then read to the group and necessary clarifications were made. Using a previous pilot trial as a guide, a period of time suitable for answering each question was allowed, after which the tape passed to the next question.

The answer sheets were collected and machine-scored, with the results placed on punch cards, which were then run through a computer for final tabulation. In addition, each answer sheet was manually scanned for handwritten answers on the back concerning other drugs used and undesirable effects from drugs.

A total of 19,948 men were surveyed, and no one refused to complete the questionnaire.

RESULTS

This survey indicated that 6,203 subjects, almost one-third (32 percent) of all men entering the Army from the Midwest in this time period, had used drugs (see table 1). The most frequently used drugs were marijuana and hashish, with respective prevalence rates of 24 percent and 16 percent. Amphetamines were next, followed by LSD, mescaline, and barbiturates. "Harder" drugs occu-

TABLE 2
Drug Use by Demographic Characteristics

Characteristic	Percentage of Total Population	Percentage of Drug Users
Race		
White	84.10	32.30

No response	0.84	—

pied the lower end of the scale, with lower prevalence rates for opium, cocaine, heroin, and morphine. Most subjects had used drugs 15 times or less. Many had taken a drug five times or less; this was true of 47 percent of the cocaine users and 46 percent of the heroin and opium users. In contrast, "softer" drugs were used more frequently; 42 percent of the hashish users had used that compound 15 or more times, compared to 19 percent of the cocaine users, 22 percent of the heroin users, and 15 percent of the opium users. Marijuana was the only drug listed on our sheet that had been used 15 or more times by more than half (53 percent) of its users.

Two-thirds of the respondents stated that a month or more had elapsed since they had used a drug. Only one percent indicated that they had used drugs within two days prior to the survey. Generally, drugs were used in commonly expected ways. Marijuana and opium were smoked by 96 percent and 93 percent of their respective users. Amphetamines were taken orally by 83 percent of their users and injected by 12 percent, while barbiturates were taken orally by 72 percent of their users. Occasionally, unusual methods of use were disclosed, such as three persons who admitted injecting hashish and six percent of the DMT users who admitted injecting that compound.

There was little racial difference between whites and blacks in overall drug use, with whites having a 32-percent usage rate and blacks, 31 percent (table 2). The small sample of Indians had a 35-percent usage rate. However, differences in racial prevalences were noted for each drug used (table 3). Prevalence of marijuana usage totaled 25 percent for white users versus 21 percent for nonwhite users. Hashish usage was 16 percent for whites and 12 percent for nonwhites. LSD prevalence for whites was nine percent and for nonwhites, seven percent. Opium had rates for whites of four percent and for nonwhites, two percent. Barbiturate usage for whites was ten percent and for nonwhites, 18 percent. Amphetamine rates for whites were 12 percent and for nonwhites, 28 percent. Heroin had prevalence rates for whites of two percent and for nonwhites, four percent.

Almost 40 percent of the Jews in the survey indicated that they had used drugs (table 2). Persons professing no religious affiliation were next with 37 percent, and Catholics were third with 29 percent. There were higher rates of drug use in more populous areas, with urban areas having rates of 36 percent compared to 17 percent in rural areas (i.e., populations under 2,500). Rising family income was associated with increasing drug use, with men from families with the highest income (i.e., more than $13,000 per year) having a 39-percent prevalence rate and men from the lowest (less than $4,000 per year), an 18-percent prev-

TABLE 3
*Use of Specific Drugs by Racial Groupings (in Percentages)**

Drug Used	White (N=16,776)	Nonwhite (N=2,870)
Amphetamines	12.24	28.48
Barbiturates	9.90	18.07
Cocaine	3.58	5.22
DMT	2.15	1.94
Hashish	16.80	12.91
Heroin	2.40	4.49
LSD	9.64	7.69
Marijuana	25.64	21.23
Mescaline	9.76	6.12
Morphine	1.54	1.88

*Percentages total more than 100 percent because of multiple-drug users.

alence rate. Prevalence of usage for those who started college but did not complete it was 32 to 37 percent, depending upon the year in which they dropped out, whereas graduates had a prevalence rate of 25 percent.

Only a two-percent difference in rates of drug use was noted between volunteers and draftees. The prevalence rate among volunteers was 30 percent and among draftees, 28 percent. Rates among reserves and National Guardsmen were lower, with 24 percent and 22 percent, respectively. With reference to marital status, divorced men displayed the highest prevalence rate (38 percent) and married men, the lowest (20 percent). Persons who had lived with both parents until age 16 had prevalence rates for drug abuse of 25 percent, versus 33 percent for those who had not.

Age at onset of drug use was generally in the late teens, but some subjects had started sniffing glue at an earlier age, with a mean of 14 years (table 4). Apart from glue sniffing, 14 years was the earliest age of onset for any other drug used. Subjects had first used amphetamines and the hallucinogens DMT and psilocybin as early as age 14; barbiturates, heroin, LSD, marijuana, and STP as early as age 15; and cocaine, morphine, and opium at 18 years. The youngest mean age of onset for use of any chemical other than glue was 17 years, for both LSD and STP. Mean age of onset for marijuana use was 18.1 years.

Reasons given for drug use were mainly curiosity (41 percent) and to get a high (29 percent). Seven percent listed going along with friends as their reason for drug use. Almost all users (99 percent) indicated that they were first introduced to drugs by friends. Two percent stated that they had used drugs other than those listed. Five percent stated that they had suffered undesirable effects from drugs. The results of the responses concerning side effects and other drugs used will be dealt with in a later article.

TABLE 4

Average Age and Range of First Use of Specific Drugs

Drug Used	Age (Years)	
	Average	Range
Amphetamines	17.1	14–23

LSD	17.0	15–23
Marijuana	18.1	15–23
Mescaline	18.4	17–25
Morphine	18.7	18–22
Opium	18.3	18–20
Psilocybin	18.8	14–20
STP	17.0	15–21
Glue	14.6	11–19

DISCUSSION

Although this survey was conducted in a military setting, it in fact involves a young male civilian population. All respondents had been in the Army two days or less when surveyed. Prevalence rates varied considerably each month, fluctuating from 25 percent to 34 percent. In the fifth month, procedures were altered and the subjects did not have complete privacy during completion of questionnaires. During this month the prevalence rate dropped to 25 percent. In the sixth and final month, original testing procedures were resumed, and prevalence rates rose to 32 percent. This would seem to indicate that privacy of respondents is an important factor in obtaining valid responses to drug abuse surveys.

Most of the persons admitting drug use appeared to be casual users or experimenters. This was supported by the facts that: 1) few had used any particular drug more than five times, 2) 97 percent stated that they did not plan to continue using drugs, 3) 79 percent used drugs in a social or group setting, and 4) more than half (57 percent) did not pay for the drugs they used. In addition, relatively few used the more pathological intravenous method, even for heroin. Less than half of the heroin users and less than one-third of the morphine abusers injected these respective compounds. But our survey did reveal a small core of confirmed drug users. Fifteen to 20 percent of the drug users indicated that they had used hard drugs 15 times or more and two percent of the drug users indicated that they planned to continue using drugs. Unfortunately, computer time was not available to delineate the demographic characteristics of these people.

Very few subjects indicated that they had used drugs in the week prior to testing. This may have been due to the unavailability of drugs during the transition period between home and the Army, fear of being apprehended in a new situation, or having experimented and discontinued drug use. If urine tests for the presence of drugs are unreliable two or three days following last drug use, then reception station testing would have the potential of detecting only one percent of all drug users coming into the military. Thus reception station urine testing appears to be an ineffectual detection procedure for drug users.

Admission of unusual methods of drug use, such as injecting glue (two persons) or hashish (three persons), indicates a reckless disregard for personal safety and demonstrates an ignorance of the deleterious effects of the various methods of drug intake, or it could simply indicate an error in questionnaire completion. However, clinical experience has revealed that sometimes individuals do inject these substances intravenously.

Racial differences were most notable for types of drugs used rather than for total drug use. There were great racial differences in the sample, with whites comprising 84 percent of the population and blacks, seven percent. For ease of comparison the total nonwhite population was compared with the white population. Nonwhites' use of amphetamines, barbiturates, and heroin was twice that of the whites, while cocaine had a three-percent prevalence

rate among whites and a five-percent rate among nonwhites. In contrast, whites tended more toward the use of marijuana, hashish, and hallucinogens.

The largest religious group, Protestants, had the lowest prevalence rate (26 percent), whereas the smallest religious group, Jews, had the highest rate (39 percent).

Higher drug use in more populous areas may indicate greater accessibility of drugs in urban areas, while rising use with higher incomes might mean that more money is available for self-indulgence, including drug use. However, most drug users in our population did not pay for their drugs, so higher family income may not have had a direct causal relationship with increased drug use. Lower prevalence rates among college graduates may indicate greater ego strength, personality stability, and self-control in persons who graduate, as opposed to those who do not. Marital and family stability appear to influence drug use, with unstable marital and family situations being associated with a higher prevalence of drug use.

There was a wide age range (11 to 25 years) for the onset of drug use, but most users had started when they were 17 or 18. Glue sniffing was the earliest form of drug abuse, and the average age for onset of use was 14 years, the youngest mean age for starting any drug. We would like to be able to say that our figures concerning average age of onset indicate that drug abuse is not creeping into junior high schools and grade schools as has been recently feared. However, our respondents were in junior high school at least four to five years ago, making such a statement invalid.

One of the startling findings of the study is that 99 percent of the users indicated that they were first introduced to drugs by friends. What portion of these friends were also pushers is not known, but it probably was small. Also, seven percent of the users indicated that they had first used drugs to go along with their friends. These figures reinforce the concept of the importance of peer relationships in drug abuse, as opposed to what adults and other authority figures may say. This indicates that drug abuse education programs with small group discussions may be more effective than lectures by an "expert" adult.

Ninety-seven percent of the users indicated that they did not plan to continue drug use. If this is true, it is encouraging and may reflect either unpleasant effects or disappointment in the actual drug effects. Since only five percent of our respondents admitted having unpleasant effects, the latter may be more likely. However, there does remain the possibility that despite assurances to the contrary, these men may have feared being identified and watched if they admitted their intentions of further drug use.

Steps in the Return to School of Children with School Phobia

BY ELISABETH LASSERS, M.D., ROBERT NORDAN, PH.D., AND SHEILA BLADHOLM, M.S.W.

Although a variety of methods for the treatment of school phobia has been proposed in the literature, most writers agree that returning the child to school as soon as possible is of primary importance. The authors discuss eight steps that they have found to be successful in helping the child return to school and helping his parents to keep him there. Case reports that illustrate the application of these steps in practice are also presented.

CHILDREN WITH SCHOOL PHOBIA present a difficult problem that is very upsetting to the child, his family, the community, and the therapist. Suddenly, for little or no apparent reason, the child refuses to go to school. He insists on staying home and may complain of aches and pains. When his parents urge him to go to school, he may cry, perspire, become pale, and show other signs of severe panic that are relieved only when his parents finally allow him to stay home. The longer he stays home, the harder it becomes to send him to school, and he soon develops "school phobia."

A great deal has been written about school phobia, and many views have been expressed about the dynamics and treatment of the problem. The most thorough reviews of the literature with extensive bibliographies are those of Esther Marine (1–3) and Kahn and Nursten (4, 5). In spite of the great divergency of opinion, most authors agree that the child's early return to school is of prime importance, and the focus in this paper is on the appropriate steps before, during, and after returning the child to school (6–18). While most therapists probably use these steps to some extent, we feel that it is relevant to look at them more specifically, to relate them to the casual mention of their use in the literature, and to draw on our own experiences for particular illustrations.

SCHOOL PHOBIA

The term "school phobia" needs to be differentiated from truancy and simple school withdrawal. A "truant" is a child who is absent from school without either his parents' or the school's permission. Other children may be kept home for some reason by the parents, and this may be termed "school withdrawal." Both problems are social in nature. The child with school phobia, on the other hand, may *want* to go to school but *cannot* and becomes acutely anxious even at the thought of leaving home. To some extent, "school phobia" is a misleading term, in that it is usually symptomatic of another problem—the tie between parents and child and the resulting conflicts (4).

Most authors suggest that the basic difficulty is a mutual hostile-dependent relationship between mother and child or, much less frequently, between father and child (7–9, 19–25). While the parents overtly urge the child to go to school, they give nonverbal cues interpreted by the child as suggesting that he stay home (6–9, 21, 26–31). When these children are in school, they frequently fear that death or injury will occur to a family member, most likely as a result of their fear that their hostile wishes might come true (8, 9, 13, 15, 16, 23–25, 27, 29, 32–37). The child feels an urgent need to go home, then, to make sure that his "beloved one" is still alive and well. Frequently, there is a precipitating event, such as a death or illness in the family, or the child's own illness (8, 9, 11, 16, 21–23, 38, 39). After this acute precipitating event has passed, the child will then refuse to return to school.

RETURNING THE CHILD TO SCHOOL

The treatment of school phobia has caused considerable controversy in the literature, with approaches ranging from psychoanalytic therapy (11, 32) and "analytic first aid" (15) to child guidance approaches, conditioning (33), and other rapid treatment methods (10). An early controversy dealt with how quickly to return the child to school; although there are still some authors who feel that an early return to school may interfere with intensive therapy (24, 40), most authors cited in this paper believe that rapid return to school is essential, though they may differ over the method of therapy to be used after the child has been returned to school. Our own experience confirms this belief.

There are several reasons for returning the child quickly. The children who do go back seem to improve rapidly, while those who remain at home become increasingly anxious, so that it becomes more and more difficult to return them to school at a later date. Since a large part of the problem seems to be the mother's difficulty in letting the child go, the successful experience of his being back in school permits both the parent and the child to function in a more usual way; if anxiety continues to be a problem, it can be dealt with in psychotherapy.

The authors are with the Abraham Lincoln School of Medicine, University of Illinois, Chicago, Ill., where Dr. Lassers is Assistant Professor of Psychiatry and Pediatrics, Dr. Nordan is Assistant Professor of Psychology, and Ms. Bladholm is Assistant Professor of Medical Social Work; Dr. Lassers is also Director of Child Psychiatry, Illinois Masonic Medical Center, 923 West Wellington Ave., Chicago, Ill. 60657.

How can early return to school be accomplished? In our work, we have found that several steps are necessary which must be initiated as quickly as possible. These steps are set forth below, along with illustrative case reports.

Step I: Physical Examination

Obviously, if the child has a real physical illness that keeps him out of school, lack of attendance cannot be called "school phobia." The first step, then, in dealing with a child who is staying home because of physical complaints is to determine whether there is an organic basis for his condition. It should be kept in mind, however, that physical symptoms, mostly minor and chronic, such as headaches, gastrointestinal upsets, or mild respiratory symptoms, may be used by the child and his family as an excuse to keep him out of school, thus masking a real school phobia.

Step II: Psychiatric Evaluation

The next step is to rule out an incipient psychosis or other serious pathology, since school avoidance in such cases is usually seen as a secondary symptom rather than as a primary problem. The therapist should conduct an interview with parents and child and then determine the seriousness of the difficulties.

Case 1. Charles was hospitalized at age 13 for "chest pains" but was discharged soon after when examination revealed no organic cause for his complaints. Four months later he was brought to the Child Psychiatry Clinic because he had refused to return to school after his discharge. Charles was spending most of this time in his room, though he slept very little and had frightening nightmares; he was also fearful of members of other races and nationalities and fantasied attacks both upon them and upon members of his family. Charles was anxious, had delusions of grandeur and persecution, and had tenuous reality testing. School avoidance was thus a symptom of psychotic decompensation; immediate hospitalization was recommended.

The second purpose of the diagnostic interview with the child and his parents is to determine the individual and family dynamics involved and the precipitating event that resulted in school phobia. While certain relationships and problems might be expected, they are not always present in every case and, even when found, their expression can vary widely.

Case 2. Randy, a six-and-a-half-year-old black boy, was referred to the clinic after he had been out of school for nearly a year. When he first started kindergarten, he cried and the teacher suggested that he stay home until the following year. The next September, he had a successful first day at school, but on the second day he was hit by a car and suffered a broken leg. After being in the hospital in traction for three weeks and at home in a hip spica cast for seven weeks, he had sufficiently recovered to return to school, but he refused.

Randy came from a severely disorganized ghetto family. He was the eighth of 11 children, and his parents were divorced when he was three and a half years old. His maternal grandmother, to whom his mother was very close, had died when his mother was pregnant with Randy. The mother herself had a history of depression and suicidal attempts. Her tenth child was born two months before Randy was to start first grade, and she was pregnant with her 11th at the time of the interview. Randy's older sister, who had taken a mothering role toward him, had also been pregnant at the time he started kindergarten.

While Randy was not able to verbalize his problems easily, his play fully revealed his concerns. While in the hospital he had been quite lonely, and he was still angry that his mother had not visited him. He knew that his mother was expecting another child and feared that he would again be left alone. Past desertions—by his father, by his mother during other pregnancies, by his sister during hers—all contributed to his anger and his fear of being abandoned once again. The anger could not be expressed, however, since he still needed his mother, and it is likely that he felt that he must stay home to make sure that his mother had not been destroyed by the destructive fantasies he had about her. Randy was still concerned about the injury to his leg, with unresolved castration fears.

Randy's mother was overwhelmed by her own problems and those of her family. Though she was irritated by Randy's demands and clinging behavior, she also worried about him and "loved" him while he was ill and at home. It may be that he was a "special" child to her, since she was pregnant with him when her own mother had died and he had provided comfort to her then; but at the same time, she may have had strong feelings of rejection for him. Whatever the reason, her dependence upon him and her communication of these concerns to him did not promote his easy return to school.

Step III: Finding a Therapeutic Ally

One of the most important steps in returning the phobic child to school is to find one or more persons who can function as a source of strength. This can be someone in the family or someone outside—a teacher, a minister, or even a family friend. This person acts as a kind of aide to the therapist—someone who is more often present and more available to the family on a day-to-day basis, and who can act both as an agent of external control and as a support to parents and child.

Case 3. In the case of Sally, an eight-year-old girl, the family physician provided the extra support that was needed to get her back in school. It was he who had initially referred her to the clinic, since his own examinations and those of several other physicians indicated that there was no physical basis for the child's complaints, and it was his insistence that finally brought the family to the clinic. Sally's complaints of headaches and nightmares began when the family had moved just before school started; this had been the fifth such move in five years, and Sally had recently asked when the family would be moving again. Her mother had been hospitalized four times since Sally was born; the last hospitalization, for a hysterectomy, occurred when Sally was six and precipitated a depression in the mother that she "hid" from the children. Sally had one older sister who was said to be "bad," but who received more of the parents' approval since they prized her independent behavior.

Assessment of the case was made in close collaboration with the referring physician, who then informed Sally's mother of the findings. She put up immediate resistance to accepting Sally's problems as being emotional, indicating that Sally had had a reaction to a penicillin shot, which had kept her home for two weeks, but the doctor assured her that the "reaction" was simply the result of Sally's hyperventilation. He reiterated that he had found no physical problems in his examination and told the mother that she could best help the girl by standing firm and insisting that Sally go to school.

Although the mother agreed to the plan, the doctor felt she

was not convinced; but when the social worker checked with the mother a few days later, Sally was in school. The mother admitted that forcing a "sick" child to go to school made her feel guilty, but she was determined to follow her doctor's advice and to keep Sally in class. She asked for help in finding a local agency that would provide therapy for the girl, but later, when she was recontacted, the mother indicated that the family had not followed up on the referral since Sally was still in school and things were going well.

Step IV: The Interpretive Interview

Once the therapist has established that the child is not physically ill or seriously disturbed, has some understanding of the dynamics of the case, and has identified someone who can provide extra support, an interpretive interview is needed to discuss the problems with the family and to set up the expectation that the child can return to school immediately. The therapist should confirm that nothing is physically wrong with the child and indicate that the child is truant unless he goes back to school at once. He should show his willingness to help the family and child find ways to make his return to school easier. If the precipitating cause is obvious, it should be discussed, and fears ("Will I be a bad mother if I make him go to school?") should be dealt with sympathetically. The therapist should be understanding but firm in his resolution that the child return to school, suggesting that the only alternatives are a truancy petition or hospitalization in a psychiatric unit that has classroom facilities. A mild tranquilizer may be prescribed for a few days to alleviate some of the renewed anxiety over the return to school.

Step V: Planning

The therapist, the family, and the school should draw up plans for returning the child to class and set a date in the near future. If at all possible, a face-to-face meeting should be held so that a plan can be worked out among all those involved. In some cases, it may seem advisable to return the child gradually, through a kind of "deconditioning" process, letting him return home after part of the day or permitting him to retire to the principal's office from time to time. In other cases, a complete return may be desirable so that the child has no "outs."

Case 4. The school not only took an active part in planning the return of Jenny, age nine, but was also a source of strength for the family. Just before a minor illness that kept her out of school, Jenny's grades had begun to drop, and later, looking back, the parents realized that the change occurred after her father lost a finger in an accident at work. Jenny began to complain of sore throats and was even hospitalized with tonsillitis; she could not return to school. A crisis was reached two months later when Jenny set two fires within two days.

At the interpretive interview with the parents, it was suggested that Jenny be returned to school immediately, the next day if at all possible. The mother's ambivalent feelings came out at once—she did not want to be a "bad mother" by sending a sick child to school, nor did she want her daughter to miss so much school. With support, she was able to get Jenny off to school the following morning, but Jenny used one of her previous symptoms to foil the plan. She vomited and was sent home. Again the mother, teacher, and principal were contacted, and it was agreed that Jenny would stay in school, even if she did vomit. Jenny tried to find a way home again and was successful: she vomited down the front of her dress. At last, when a final plan of sending extra changes of clothes to school was worked out, Jenny settled down and did not remain out of school any longer.

Step VI: Support

Jenny's case and some of the others discussed show the importance of the therapist's continuing involvement in guiding and supporting the family as it made the critical adjustment of returning the child to school. Phone calls were made, office visits were arranged, and, in some cases, home and school visits were necessary. Sometimes drug therapy was necessary, usually for a limited time. Whatever the need, the therapist should make himself available so that he can provide the help and support that both parents and child need to make the return to school successful.

Step VII: Follow-Up

At the time that the child returns to school (successfully, one hopes) he, his parents, and the school should understand that the therapist will be checking at regular intervals to determine his progress. To the family, this says that the therapist is interested and still available; to the school, it indicates the therapist's willingness to continue to be involved and to provide consultation whenever the teacher or principal needs it. In the cases described here, some contact has been maintained; at last report, all the children except Randy were still in school and coping acequately.

Step VIII: Psychotherapy

Ideally, follow-up would be only one aspect of a total therapeutic plan but, although psychotherapy was offered all the families mentioned above, none accepted. Once the child was back in class and free of overt physical symptoms, the overall anxiety level was apparently reduced enough that further therapy was rejected. Although we have little information concerning the later development and adjustment of the children, neither they nor their siblings have returned to the clinic with the same or other symptoms.

DISCUSSION

School phobia frequently appears as a symptom in response to a subtle, often ambivalent, message from the mother or another family member that life is insecure and the child had better stay at home. Staying at home then leads to a vicious circle of withdrawal from the growth-promoting stimulation of learning and peer relations. further regression and withdrawal, increasing embroilment in a hostile-dependent relationship with parents, more intense anxiety, and more extreme school rejection.

At the same time, in moments of healthier ego functioning, both parents and child know that the child should be in school and, at some point, they reach out for help. If

he acts quickly, the therapist can strengthen this functioning through his own authoritative support and the temporary reliance on family members, school personnel, or someone else outside the family in order to work out a plan for the child's immediate return to school. Then, with some of the anxiety of both parents and child relieved, and the message clearly stated that the child must return to school, he can usually go back to class. Once there, the child can use the accomplishment for further growth and the symptoms usually do not reappear (12).

Although the return to school puts an end to the secondary gain of staying at home and induces growth, it does not solve the family's basic problems, for which further therapy may be needed. Unfortunately, in the cases described here, the families were not ready for treatment. It could be argued that they might have been better motivated for further treatment if they had been denied relief of the symptom, but this would be risky since school phobia itself is so crippling and becomes harder to treat the longer the child's return to school is put off.

CONCLUSIONS

This paper has focused on the specific steps we have found useful in returning the school-phobic child to school as soon as possible. The first step is to rule out any organic reasons for the symptoms through a physical examination and then to determine the dynamics of the situation through a psychiatric examination. Next the therapist should search for a therapeutic ally, someone who can support the family on a day-to-day basis through the period of crisis. With these steps accomplished, an interpretive interview can be held with the family and the expectation should be set up that the child can return to school immediately. A plan is devised in cooperation with school personnel and, during the critical first days after the child's return, frequent support is given by the therapist. Follow-up contact is made and, if possible, the family is involved in psychotherapy.

The Effects of Regressive ECT with Process Schizophrenics

BY LUIS G. MURILLO, M.D., AND JOHN E. EXNER, JR., PH.D.

An experimental group of 32 process schizophrenics was treated with regressive ECT, while a control group of 21 patients was treated with ataraxic drugs and psychotherapy. All patients were evaluated at admission and at or after discharge, using four sources of evaluation: self-ratings, psychological tests, relatives' ratings, and ratings by referring therapists. Statistical analysis of 55 variables indicated that the two groups were essentially equivalent at admission but showed significant differences on 28 of the 55 variables after discharge. All of the variables favored the experimental group treated with regressive ECT.

MAY (1) STUDIED 228 schizophrenics randomly assigned to five treatment groups. All were first admissions to a state hospital. He concluded that the administration of ataraxic drugs alone is generally the treatment of choice for the schizophrenic whose pretreatment prognosis is average or poorer. He also found that ECT is not a desirable alternative to drugs or drugs plus psychotherapy. The patients in May's ECT treatment group were treated by the conventional method. Unfortunately, studies using experimental variations of ECT have been limited, particularly as chemotherapy has gained wide use.

Regressive ECT is an experimental variation that employs more frequent treatments than is the case with conventional methods. It has been variously described as "intensive ECT" (2) and as "depatterning" when combined with sleep therapy (3, 4). Its effectiveness is not so much based on the increased frequency of treatments as on the occurrence of a "clinical" regression, which may occur after only a few treatments or may require many. The regression is marked by a state of helplessness, apathy, confusion, memory loss, speech alterations, and gross disorientation. Neurological signs of alteration in cerebral activity are evident near the end of treatment. Recovery from this state usually takes from seven to ten days. Improvement, if it occurs, is marked during this period.

Glueck, Reiss, and Bernard (5) reported the five-year follow-up of 100 patients treated by regressive ECT. They found that patients showed significant improvement, which often continued throughout the follow-up period; they could discern no serious medical complications or evidence of cerebral damage. Unfortunately, the reports concerning the effectiveness of regressive ECT have not been based on controlled investigation. For this reason, and in view of the encouraging observations on the use of this method at Stony Lodge Hospital, where the routine is to administer treatment twice daily seven days a week until regression occurs, it seemed important to conduct a controlled study to determine its merits.

The hypothesis underlying this research is that, given two groups essentially equivalent in demographic and psychological features, including severity of illness, a group treated by regressive ECT will improve as much as or more than a group treated with ataraxic drugs plus psychotherapy.

METHOD

It seemed essential to include only patients whose prognosis would ordinarily be judged as average or poorer. The criteria for "process" schizophrenia seemed most appropriate in this context (6). All patients included in the study had a poor premorbid history, chronic disorganization and detachment, and a long history of chaotic and unpredictable behavior. By no criterion applied would they be described as "reactive" schizophrenics nor would they carry a favorable prognosis.

A simple randomization design was planned but had to be abandoned because nearly half of the patients who met the selection criteria and were recommended by the admission board for regressive ECT could not be treated by this method because of the family's opposition or because physical conditions contraindicated its use. Since the hospital is not large (60 beds), it was decided to use patients recommended for but not receiving regressive ECT as controls, provided they met the criteria for process schizophrenia.

Four independent sources of evaluation were used to control for bias: 1) the patient himself, 2) two psychological tests, 3) the patient's referring therapist, and 4) the patient's closest available relative. None of the evaluators, including the patients, were aware of the purpose of the study. Further, to ensure naïveté, evaluations were collected for all patients entering the hospital between June 1970 and April 1971, even though more than half were not subjects in the study.

A total of 158 patients with various disorders were admitted during this period. Fifty-three of the 158 met the criteria for process schizophrenia and were also recom-

mended for regressive ECT by the admission board.[1] Thirty-two of the 53 (11 men and 21 women) were treated by regressive ECT; they constituted the experimental group. The remaining 21 (11 men and ten women) were treated with drugs plus psychotherapy; they constituted the control group.

Patient evaluations were collected at admission and again at discharge or seven to nine weeks thereafter. At admission each patient completed the Katz Adjustment Scale Form S (KAS-S), which yields scores for six variables (7): symptoms, performance of and satisfaction with social behaviors, expectation of social activities, and performance of and satisfaction with free-time activities. We also administered the Minnesota Multiphasic Personality Inventory (MMPI) (8), from which 16 scales were analyzed,[2] and the Self-Focus Sentence Completion (SFSC), which provides four scores relating to egocentricity (9). An EEG was also taken.

At the same time, the closest available relative completed the Katz Adjustment Scale Form R (KAS-R), which provides 13 measures of symptoms and social behaviors along with five additional scores concerning the evaluation of, expectation for, and satisfaction with the patient's performance of social and free-time behaviors (7). KAS-R items are written in everyday language and can be used easily by the lay reporter.

The referring therapist completed an Inpatient Multidimensional Psychiatric Scale (IMPS), which was selected because of the ease with which it can be used by professionals after routine observation (10). It yields scores for ten factors ranging from excitation, hostility, and paranoia to cognitive, perceptual, and motor processes, as well as a composite score for schizophrenic disorganization.

At discharge the MMPI and SFSC were administered again and a second EEG was taken.[3] Seven to nine weeks after discharge the former patient again completed the KAS-S and the relative who had rated him at admission again completed the KAS-R. The referring therapist was contacted to determine whether the patient had returned to him for aftercare and, when this was the case, the therapist again completed an IMPS.

RESULTS

A statistical analysis of the demographic data showed no significant difference between the groups regarding age, marital status, education, length of hospitalization, number of individual and group therapy sessions, and incidence of prior hospitalization. The average patient in each group was in his 30s, had some college experience, had spent about 15 weeks in the hospital, and received about 25 individual and 21 group therapy sessions. About two-thirds of the patients in each group were married and about half had been previously hospitalized. The regressive ECT patients averaged 26.3 treatments, with a range of six to 58 treatments before "clinical" regression occurred.

The data from the four sources of evaluation—self-reports, psychological tests, relatives' reports, and therapists' reports—were each analyzed separately, using an analysis of variance for repeated measures; all analyses yielded f ratios that were statistically significant beyond $p < .01$. Subsequently, t tests were performed to further identify specific areas of significance in the data from each source. Both within-group and between-group analyses were performed. A total of 55 variables was studied.

Table 1 shows the frequency of statistically significant differences between the groups at admission and discharge or post discharge for each of the four sources of evaluation. It also includes the number of variables that changed significantly within each group from the first to the second evaluation. At admission, the groups differed on only four of the 55 variables, all from the relatives' reports. The regressive ECT group was rated as more confused and bizarre in behavior, while the control group was rated as more negative and functioning less satisfactorily in free-time behaviors. At discharge and post discharge the groups differed substantially. A statistically significant difference occurred between the groups for 28 of the 55 variables, all of which favored the ECT group. Further, the ECT group manifested significant change on 42 of the 55 variables (76 percent) from the first to the second evaluation, while the control group changed significantly on ten of the 55 variables (18 percent). It seems important to emphasize that significant changes occurred between the groups in the evaluations of all four sources.

Self-Reports

The groups were essentially the same at admission, but differed significantly on two variables after discharge. The ECT patients reported fewer symptoms and a more favorable performance of social behaviors. They were also more satisfied with this performance. The control group was essentially unchanged, except that they too were more satisfied with their performance of social behaviors. In an effort to clarify the self-reported data each former patient was asked to rate his post-discharge adjustment on a five-point scale. The results are shown in table 2.

Psychological Tests

At admission both groups showed very high SFSC scores for self-focus (egocentricity) and low scores in external world focus. At discharge the control group was essentially unchanged, except for giving fewer ambivalent

[1] In all, 77 of the 158 patients were recommended for regressive ECT by the admission board; however, 24 either did not meet the selection criteria for process schizophrenia or left the hospital against medical advice before treatment was initiated.

[2] The 16 scales analyzed from the MMPI were the three validity scales (lie, frequency, and correction), the nine clinical scales (hypochondriasis, depression, hysteria, psychopathy, masculinity-femininity, paranoia, psychasthenia, schizophrenia, and hypomania), and four nonclinical scales (social introversion-extroversion, ego strength, general maladjustment, and anxiety).

[3] EEGs were also taken from the regressive ECT group 12 to 15 days after their treatments were terminated.

TABLE 1
Summary of Statistically Significant Differences Within and Between Groups

Source	Number of Patients		Number of Variables	Significant Differences Between Groups		Number of Variables Significantly Changed	
	Experimental Group	Control Group		Admission	Discharge or Post Discharge	Experimental Group	Control Group
Self-reports	32	21					
KAS-S			6	0	2	3	1
Psychological tests	32	21					
MMPI			16	0	8	13	0
SFSC			4	0	3	3	1
Relatives' reports	27	18					
KAS-R			18	4*	7	13	4
Referring therapists' reports	22	15					
IMPS			11	0	8	10	4
Total			55	4	28**	42	10

*Two of these favored the experimental group and two favored the control group.
**All favored the experimental group.

responses. The ECT group showed a significant reduction in self-focus scores and a significant increase in external world focus scores, along with a corresponding reduction in ambivalent scores.

On the MMPI the groups were extremely similar at admission, manifesting pathologically high scores for eight of the 16 scales studied: depression, hypochondriasis, psychopathy, paranoia, psychasthenia, schizophrenia, hypomania, and general maladjustment. At discharge, the control group had not changed significantly, while the ECT group manifested significant change on 13 of the 16 scales and differed from the controls on eight of the scales, including seven of the nine basic clinical scales. At discharge none of the scores from the ECT group fell in the pathological range (8, 11).

Relatives' Reports

Though they differed only slightly at admission, the relatives' ratings differed markedly after discharge. The ECT group was rated as significantly less suspicious, anxious, and hyperactive and as showing fewer signs of general psychopathology than controls. The ECT group manifested significantly more stability and performed more favorably in both social and free-time activities. The post-discharge KAS-R report profiles were also compared, by group, with relatives' ratings of 133 day-care psychiatric patients, a second group of 51 discharged state hospital patients who showed no relapse after one year, and a third group of 450 nonpsychiatric subjects. The ECT group's profile generally fell between those of the day-care and nonrelapsed groups, while the control group's profile was very similar to that of the day-care sample.

Therapists' Reports

The evaluations of the referring therapists were the smallest in number of the four sources of evaluation. Not all patients in either group were rated by referring therapists and not all returned to the referring therapist for aftercare. The data derived from these evaluations were consistent with the data obtained from the other sources. At admission the groups did not differ on any of the 11 variables on the IMPS. After discharge, the groups differed significantly on eight of the 11, all of which favored the ECT group. The control group scored significantly higher in excitation, paranoia, perceptual disorganization, retardation, and motor disorganization, and showed increased hostility, grandiosity, and cognitive disorganization. In effect, the referring therapists rated the control group after discharge as essentially unchanged or worse.

EEG Evaluations

One of two consulting neurologists reviewed the admission and discharge EEGs. The neurologists also did blind ratings of EEGs of the ECT group taken 12 to 15 days after treatment was terminated. They judged all 53 admission and discharge protocols to be within normal limits. They noted abnormal alterations in delta activity in the EEGs of the ECT group taken shortly after treatment.

TABLE 2
Patients' Ratings of Their Adjustment After Discharge

Adjustment	Experimental Group	Control Group
Improved considerably	14	4
Improved slightly	11	6
Unchanged	5	3
Slightly worse than before	1	5
Considerably worse than before	1	3

DISCUSSION

The data presented appear to confirm the basic hypothesis of the study, that is, that the group treated by regressive ECT would improve as much as or more than the group treated by drugs plus psychotherapy. Both groups showed improvement, but the ECT group apparently showed the greater gains. The discharge and post-discharge evaluations showed the ECT group had relatively inconsequential symptomatology or behaviors commonly associated with severe disturbance.

Close examination of the results provides some clues about the symptomatic and behavioral differences between the groups at and after discharge. The discharge evaluation was derived from two psychological tests. On one, the SFSC, the ECT patients were considerably less egocentric and considerably more outer-world-oriented, while the control group remained highly self-centered. On the second test, the MMPI, the ECT patients showed profiles that were essentially free of the high T scores commonly associated with severe disturbance, while the profiles of the controls remained generally high for hypochondriasis, paranoia, hysteria, and hypomania and particularly high for depression. These data can be interpreted to suggest that, at discharge, the ECT patients were more concerned with affective control and social competency, whereas the control group were angrier and more preoccupied with themselves, especially with their health, and had become more interpersonally distant, with fewer affective controls.

The evaluations from the three sources taken seven to nine weeks after discharge appear to support this interpretation. The self-reports indicated that ECT patients had fewer symptoms and were performing more social behaviors. The relatives' reports, which are possibly the least amenable to the influence of any bias, described patients in the regressive ECT group as having fewer symptoms, being less anxious, and using free time more effectively. Conversely, the controls were rated as more suspicious, less stable, and more anxious than desired, and as functioning less effectively in social and free-time behaviors. The evaluations of the referring therapists provide added confirmation. They rated the ECT patients as substantially improved on nearly all of the variables measured by the IMPS. The controls however, while improving moderately for some variables, showed a paradoxical increase in hostility, motor disorganization, and cognitive dysfunction.

On the basis of these findings it seems reasonable to speculate that the major behavioral differences between the two groups at and after discharge occurred in two broad areas: social interaction and control of affect, especially negative affect. All sources of evaluation, including the patients themselves, reported that the controls, as a group, did not make the more socially desired responses to the same extent as did the ECT patients. They were apparently still uneasy in interpersonal situations, possibly as a function of their concern with their health. That phenomenon may have generated the perceived symptoms of paranoia, irritability, and anger or depression. The regressive ECT patients appeared to have somehow learned to cope more effectively with their emotions. They interacted in social situations in a less anxious, more profitable manner. It would be unrealistic to suggest that they are completely "normal" but the data do support the contention that they are considerably different from other groups of schizophrenics and more similar to non-psychiatric groups.

It is impractical to speculate about the causes for these changes since there are few "hard" data on ECT. Cameron (3) has suggested that the amnesic effect is crucial to improvement. Ottosson, among others, has indicated that producing a convulsion is necessary to obtain the desired effect (12). Obviously, the frequency of occurrence of convulsions in regressive ECT plays some role. Kalinowsky (13) has summarized the problem of understanding ECT quite well with his reminder that no theory of ECT has been developed that is sufficiently comprehensive to be taken seriously.

Finally, there are some important cautions that should be included here. The first concerns the experimental design of our study. Pure randomization was not used. The controls, although they met the selection criteria and were recommended for regressive ECT, were not selected randomly but by such factors as the family's unwillingness to approve ECT or, in a few instances, precluding physical factors. Thus, even though the two groups appeared to be highly similar at admission, it is possible that they were somehow different. We hope that the use of external evaluations by naïve evaluators provided an adequate control for this flaw. Secondly, it is difficult to identify the extent to which treatment afforded the control group truly approximated the model used by May (1). In this context it is important to emphasize that the patients were all treated in the same environment thereby limiting the extent to which findings might be generalized. Lastly, but possibly most importantly, the period of follow-up was not very long. While the results two months after discharge were encouraging, data from at least one year after discharge would be more reassuring. A study to obtain such data is currently under way and only after those data have been analyzed can more definitive statements be made concerning the effects of regressive ECT with schizophrenics.

Questions of the Month

For each of the incomplete statements or questions below, ONE or MORE of the completions or answers given is correct. Choose:

A if only *1, 2, and 3* are correct,
B if only *1 and 3* are correct,
C if only *2 and 4* are correct,
D if only *4* is correct,
E. if *all* are correct.

Question 1

A psychiatric disorder is likely to be associated with which of the following?
(1) Systemic lupus erythematosis
(2) Acute intermittent porphyria
(3) Carcinoma of the pancreas
(4) Huntington's chorea

Question 2

Genetic disorders due to abnormal carbohydrate metabolism include
(1) amaurotic idiocy.
(2) gargoylism.
(3) xanthomatosis.
(4) galactosemia.

(The Questions of the Month are from the Self-Assessment Program of the APA. The answers are supplied on page 277 of this issue.)

The Psychological Evaluation of Patients for a Kidney Transplant and Hemodialysis Program

BY ROGER P. GREENBERG, PH.D., GARY DAVIS, PH.D., AND RONALD MASSEY, PH.D.

Psychological evaluations over a three-year period of 24 patients with kidney disease revealed very little evidence of gross emotional maladjustment. Most of the patients did seem to have experienced organic losses in intellectual functioning and they appeared to have limited amounts of energy available for coping with stress and limited affective responsivity. The authors emphasize the benefits of properly preparing such patients for psychological testing in order to allay their fears, increase their tolerance to stress, and aid in obtaining the best possible picture of their strengths and capabilities.

IN RECENT YEARS there has been a good deal written about candidates for hemodialysis and kidney transplant programs (1–5). As the programs have expanded and progressed, it has become increasingly obvious that these patients are subject to tremendous psychological stresses and require major expenditures of psychic energy in order to adapt to the strains of illness and the necessary medical procedures.

The clinical psychologist has come to play an important role in helping to evaluate the patients' level of functioning and ego resources for successful adaptation to an extremely demanding life situation. In addition, psychologists and psychiatrists have tried to help the medical team anticipate psychological problems and to devise approaches for particular patients. The ability of psychologists to significantly predict patients' future adjustment to such programs has been documented by Sand, Livingston, and Wright (6). Such predictions are particularly useful because of the current scarcity of treatment facilities, which entails selection problems, and the need to deal therapeutically with potentially severe emotional reactions in certain patients.

The present paper is a brief report of the conclusions and observations drawn from reviewing the data obtained from psychological evaluations of 24 patients over a three-year period in a university hospital transplant program. Our aim is to broaden the base of the relatively few studies in the literature and to discuss some of the problems and issues raised in performing evaluations of these patients.

At the time this paper was written, the authors were all with the Upstate Medical Center, State University of New York, Syracuse, N.Y. 13210, where Dr. Greenberg is Associate Professor and Coordinator of the Psychology Internship Program, Department of Psychiatry, and Drs. Davis and Massey were interns.

PREPARATION FOR EVALUATION

It has been our experience that potential transplant patients confronted with having to go through psychological testing often react with either fear or anger. The fear is probably most often attributable to the patients' feelings of vulnerability, since they experience a loss in intellectual functioning as a result of uremia. Abrams (1) has pointed out that uremia usually leads to some degree of "organicity," with difficulties in attention-concentration, visual-motor coordination, and nonverbal abstraction. In many cases patients may have the unrealistic feeling that they will not be admitted to the program if they cannot answer some of the test questions put to them.

Patients who respond with anger seem to be defending against their fears by angrily asking, "What does this testing have to do with my physical problems?" Both the fear and the anger often lead to the same result, namely, that the patient is hesitant to be evaluated and resistant in the testing situation. Such attitudes and expectations lead to many practical problems. For example, we have found that these patients, if they are out of the hospital, tend to cancel testing appointments much more frequently than other types of patients.

Greenberg and associates (7–9) have shown in a number of studies of the psychotherapeutic relationship that the nature of the message given to patients before they ever meet the therapist can affect their perceptions of the therapist and their willingness to cooperate with him. Greenberg (10) has also pointed out, utilizing evidence from the literatures of medicine, social psychology, and psychotherapy, that "referral messages" play an important role in obtaining the utmost in patient confidence, cooperation, and willingness to disclose and share feelings. The positive effects of structuring information before treatment have already been demonstrated for the recovery of surgical patients (11–13) and the improvement of psychotherapy patients (14, 15).

These findings seem particularly relevant for patients with kidney disease who are about to have psychological testing. We have found that the evaluation process can be significantly facilitated by giving time and care to preparing these patients for the procedures. Simply telling a patient that he is scheduled for blood tests and psychological testing does not seem sufficient. The two types of tests are not equivalent objectively or in the minds of patients. Furthermore, a large number of patients are not prepared for the fact that the testing will last a number of

hours and will require their cooperation.

Patients appear to be more receptive when they are told explicitly that psychological testing is required to aid in knowing as much about them as possible. The more that is known about their strengths and difficulties, the easier it will be to help them. By realistically providing the patients with information about why testing is needed, along with some idea of what it will be like, we have found it easier to gain the patient's cooperation and, hence, the best possible picture of his strengths. While these comments may seem like common sense, we have found that a rather high percentage of patients referred from medical services either do not know they have been scheduled for evaluation or have absolutely no idea about the kind of testing they will be faced with.

Needless to say, under such conditions many patients soon get the idea that there is little concern for them as people and that little reliance is being placed on their cooperation or capabilities. Providing appropriate referral information can help the patient to feel that he too is responsible for the course of treatment and that he too is playing an active part in the process. This would help to foster a doctor-patient alliance and thereby may even aid the therapeutic process beyond its value in the evaluation procedure.

INTELLECTUAL EVALUATION

Because of the nature of renal disease, there is always some potential for cerebral organic loss. Some researchers (1) feel that renal disease is always accompanied by some degree of organic impairment and that an intellectual evaluation is therefore necessary as part of the overall psychological evaluation to aid in the assessment of the degree and nature of the organicity. The level of intellectual functioning for the 24 kidney patients in the present sample was assessed by the Wechsler Adult Intelligence Scale. The full scale IQs ranged from 57 to 118, with a mean of 98.2. For the following discussion, deficit or loss was operationally defined in terms of a performance at least one standard deviation below the mean on any subtest tapping a particular area of functioning.

The evaluations indicated that most of the patients showed losses that would be consistent with a hypothesis of organicity. Specifically, 21 of the 24 patients showed signs of deficit in one or more areas. Particularly significant was the finding that 16 showed impairment of visual-motor coordination and 14 had suffered some deficit in their ability to learn new material. In addition, impaired attention-concentration was noted in five patients, four showed some loss of abstracting ability, four had impaired judgment, one showed loss in judgment and abstraction, and one had some loss in judgment, abstraction, and attention-concentration.

These data lend clear empirical support to the contention that renal disease results in organic-like losses in intellectual functioning in most cases. However, they also suggest that the loss may not be inevitable and that it may take different forms in different people. Future research may be aimed toward the question of whether the kind of loss experienced is mediated by such variables as the type of disease and its chronicity. It is also an open question as to whether losses can be significantly reversed after a successful transplant.

The finding of intellectual impairment in most kidney patients has implications for their convalescence and recovery. Depending on the degree and nature of the impairment, the patient may be rendered unable to care for many of his medical needs and may be more dependent on others. Some of the patients may not be able to function at their previous levels of occupation, and in this case the evaluation, in outlining the patient's strengths, may give some indication of the ease with which he might be retrained for another job.

Some of the patients in our sample are learning the dialysis procedure in order to eventually be chronically dialyzed in their homes. The dialysis procedure is relatively complex and requires an ability to respond quickly and appropriately in an emergency. Thus the finding that most of the sample patients showed particular losses in visual-motor coordination and ability to learn new material appears particularly relevant, since these losses might limit the patients' ability to participate actively in the learning and performance of the dialysis procedure. The intellectual evaluation in our program is geared toward assessing whether or not the patient is impaired to the point of not being able to care for his own needs, consequently endangering his well-being. The present data raise this as a possibility in many cases. Clearly there would be significant value in research that specifically documented the types and levels of skills necessary to deal with the home dialysis procedure.

It should be noted that our study sample was markedly different in terms of mean IQ and IQ range from the Sand, Livingston, and Wright (6) sample, which had a mean IQ of 115, with a range of 94 to 143. They ascribed the fact that their sample was well above the national norms for intelligence to the probable informal preselection of patients suggested for candidacy by referring physicians. The large IQ difference between the two samples suggests that the patient populations in different centers may not be equivalent on many dimensions and that caution must be used in generalizing the findings from any one study. However, our sample's mean IQ is closer to the population mean of 100 and hence may be a more representative sample than the one previously reported.

PERSONALITY EVALUATION

Personality evaluations in our program are based on information both from interviews and from extensive psychological test batteries, including such projective tests as the Rorschach. The aim of the evaluation is to explicate how and with what ego resources the candidate is coping with the stress of renal failure and how he may be able to cope with future major surgery or dialysis. Perhaps the greatest psychological stress the patient will have to face is the waiting period during the weeks or

months before a kidney becomes available. At this time the medical regimen is especially stringent, physical energy may wax and wane according to levels of urea toxicity, and the patient may be spending at least two days a week in the hospital being dialyzed. Mere survival during this indeterminate period can become an extremely stressful process.

With regard to dialysis candidates, Sand, Livingston, and Wright (6) have demonstrated that the patients who are seen as adjusting most successfully seem to be different from the less adaptive patients in showing higher intelligence, less defensiveness about admitting to anxiety or emotional difficulty, less reliance on emotional defenses involving physical symptoms (e.g., hypochondriasis and hysteria), and more satisfactory emotional support from family members. They seemed particularly surprised that their sample was free from gross psychological disturbances (e.g., psychoses) and suggested that the relative stability of their patient sample might be in part an artifact of the informal preselection of patients.

As noted previously, the patients in our sample seemed to have been less select, at least with respect to intelligence. Nonetheless, the results of our study are strikingly consistent with the previous findings. None of our candidates was found to be schizophrenic. None exhibited hallucinations, delusions, or thought disorder. While the performance of a few candidates indicated some impaired judgment, the reality contact of almost all the patients was quite good, considering their stressful life situation. It must be emphasized, however, that some candidates maintained effective reality testing at the price of limiting their involvement with the environment and by denying affect-arousing stimuli.

In general it was quite striking how well most patients adapted to the necessity for transplant surgery. The data from this study and the previous report of Sand, Livingston, and Wright strongly suggest that it is the rare person who breaks down psychologically under the stress of this life-and-death situation. Thus one should not consider signs of severe depression, personality disorganization, or thought disorder as typical for this type of patient.

The most consistent finding in our evaluations of patients with renal failure was a significant decrease in the amount of energy available for coping with stress. This lack of energy was manifested chiefly by lowered levels of responsivity and affective arousal. Many of the patients seemed to resign themselves to their problems while withdrawing investment from the world about them and becoming passive recipients of medical treatment. While this lack of resiliency and energy was typical of most patients, a few were able to maintain their concern for the world and attempted to cope actively with their problems.

As noted, our patient sample exhibited significantly lowered affective arousal. On projective testing, half of the 24 patients did not respond to affective stimuli at all and eight appeared to have a great deal of difficulty handling affect once it was stirred up. Only four of the 24 patients were judged to be responding appropriately to affect-arousing stimuli. Thus, the degree of psychological stress kidney patients deal with was shown by the finding that most patients are either heavily defended and don't respond to affective stimuli or, if they do respond, they have trouble maintaining control and modulating their responses with ideational defenses. As is consistent with the literature (3), most of our patients appeared to employ the defense mechanism of denial in attempting to keep from awareness the gravity of their situation. They simply did not wish to face their own feelings regarding renal failure, the usually extended period of hemodialysis, and the prospect of a transplant. If affect did appear, it tended to take the form of either depression or anger. This observation is also quite consistent with previous reports (2, 3).

The resistance against looking at the implications of their illness made it very unlikely that the average candidate would have worked through his feelings to the point of having both a realistic appraisal of the situation and positive expectations about the future. Most candidates seemed to have defended against recognizing their fears of death, depression, and anger at becoming ill. Further, there was the hard-to-accept notion that a transplant would mean that someone else would have to lose either his life or his kidney. One patient, for example, was extremely hesitant to admit he was listening to the radio during the Fourth of July weekend in the hope that an accident would provide a victim with matching kidney tissue.

The tendency of candidates to refrain from actively worrying about and dealing with their problems and treatment may have negative prognostic implications. Janis (13), in his delineation of the theoretical concept of the "work of worrying," has emphasized the potential benefit to surgical patients of a moderate amount of anticipatory fear in developing tolerance to stress. While positive prognostic expectations are desirable, the work of Janis (13), Egbert and associates (12), and Andrew (11), among others, has strongly suggested that stress tolerance on both physical and emotional levels is increased when patients are led toward making realistic appraisals of their current and possible future conditions.

CONCLUSIONS

In sum, the present study is supportive of observations in the literature and adds to the generality of the conclusions drawn. As in the one previous study that used data from psychological tests, we found very little evidence of any gross emotional maladjustment in our patient sample. Our results also lend empirical support to the speculations of others that most candidates for renal transplant exhibit behaviors that are, at least in some areas, consistent with a hypothesis of organic losses in intellectual functioning. Within the sphere of personality most patients seem to be defending heavily against recognizing the seriousness of their illness. Responsivity tends to be lowered as patients withdraw into themselves, and

affect is either denied expression or appears with little control once it is stirred up.

Our experience strongly suggests that psychological factors play an important role in the individual's ability to adapt to the stresses of renal failure, dialysis, and transplant. It seems clear that more reports from other centers are needed to broaden the base of the few studies in the literature as well as to help increase the effectiveness of current evaluations and treatment programs.

The Volunteer Rescue Squad: The Impact of a Group on the Psychological Adaptation of Its Members

BY GORDON W. KEATING, M.D., WALTER A. BROWN, M.D., AND KAY STANDLEY, PH.D.

Young rescue squad volunteers were studied to ascertain some of the developmental determinants of rescue work and to define aspects of the culture of the squad and relate these to the personal development of its members. The authors suggest that squad membership may serve important adaptive functions for the individual: in mastering past traumas, becoming independent from the primary family, and in developing self-control and competence. They indicate the need for further study of the contribution of voluntary group membership to the individual's development and adaptation; there may be important implications for various types of therapy and for community consultation.

MOST PEOPLE consciously or unconsciously avoid exposure to situations of injury, violence, and death. However, volunteer rescue workers confront such situations regularly and without the usual compensations and clearly defined roles of the technician or professional. This study focuses on a volunteer rescue squad and some of its members.

Although the socioeconomic characteristics of volunteers have been studied (1), behavioral research has not focused on the psychological determinants of membership in specific voluntary organizations or on the closely related problem of the relationship of volunteer activity to the current psychological adaptation of the individual. Although persons with shared vocational and avocational interests have been studied from the individual psychodynamic point of view—e.g., Peace Corps teachers in Ghana (2), jet pilots (3), missionaries (4), and disadvantaged adolescents in the Job Corps (5)—none of these studies has been particularly concerned with the effects of group membership.

The importance of group membership and group process to the psychological adaptation and growth of the individual was recognized by Hamburg and Adams in their recent review of coping behavior (6). Membership in certain voluntary vocational or avocational groups may represent adaptations to particular environmental stresses or intrapsychic conflicts. In many cases the relevance of the group to the problems of the individual members is obvious, e.g., Alcoholics Anonymous, but in other groups the function of helping individual members to cope may not be explicit or even intended.

The objectives of our study were to: 1) investigate some of the developmental determinants of rescue work and 2) define aspects of the culture of the squad and relate these to the personal development and adjustment of its members. We postulated that certain events in the childhood or adolescence of a volunteer might relate to his becoming a squad member and that membership in the squad might promote adaptive coping with some developmental tasks of late adolescence and early adulthood: developing an integrated identity, achieving self-respect, and attaining independence from the family of origin. Moreover, helping injured people in situations of violence, injury, and death might help the volunteer to cope with his aggressive impulses, to master past traumatic events, or to compensate for past failures or inadequacies.

METHOD

The subjects were recruited from a single volunteer rescue squad located in a metropolitan suburb. Subjects were asked to complete a battery of questionnaires and psychological tests in two separate sessions totaling about two and one-half hours. In addition, five subjects were interviewed and given the Thematic Apperception Test (TAT).

The test battery for the main sample consisted of the following measures: 1) the standard booklet form of the Minnesota Multiphasic Personality Inventory (MMPI), 2) Rotter's Internal-External Control Scale (7), 3) the Interpersonal Checklist (8), 4) a medical questionnaire on the history of serious illness and accidents involving the volunteer or members of his family, 5) a questionnaire concerning education, marital status, occupation, family background, and details about squad membership, and 6) a questionnaire concerning perceptions of parental attitudes about the rescue squad, reasons for joining and remaining in the squad, qualities of a good rescue worker, and feelings about dealing with injured people.

RESULTS

Description of Squad and Membership

The squad has been in continuous existence for 30

Dr. Keating is a Fellow in Child Psychiatry in the Child, Adolescent, and Family Programs, Department of Psychiatry, University of Washington School of Medicine, Seattle, Wash. 98105. Dr. Brown is Assistant Professor of Psychiatry, Yale University School of Medicine, New Haven, Conn., and Dr. Standley is a research psychologist in Washington, D.C.

years. Currently there are about 60 active members organized into seven teams of eight or nine members, including a captain and a lieutenant. The daily management of the squad is the responsibility of the chief, deputy chief, and an assistant chief. Financial and organizational planning are handled by a board consisting of ten people, including the chief and certain associate members (older men who were formerly active volunteers). All leaders, including the captains and lieutenants, are elected democratically by the active members. New members are given probationary status for six months, after which time they are elected to regular membership by a three-fourths majority of the regular active members.

The squad headquarters serves as the center for all rescue operations and for other business and social functions. The squad is well equipped with rescue vehicles and equipment, which the members maintain and operate. There are programs of instruction on first aid and proper use of equipment. In some ways the squad resembles a fraternity, with its raucous parties, competitive sports, and social subgroupings. On the other hand, the squad is much more than a fraternity because of its goal of providing aid and transport to the injured.

Our sample does not reflect the characteristics of the entire squad, since the study involved only active members below the rank of assistant chief. The sample contains about half of the active members, including representative numbers of probationary members, privates, lieutenants, and captains.

Length of membership in the squad varies in our sample from a few months to more than six years. Most members joined by the time they were 21. Time spent in squad-related activities varies from a minimum of about eight hours per week up to 60 or more hours per week. Only three subjects did other types of volunteer work, and only ten were members of other social or service organizations. About two-thirds of the sample were influenced to join the squad by other volunteers.

Social and Family Characteristics

The median age of the sample is about 22 years, with a rather even distribution from ages 17 to 27. Twenty-six of the 33 men in the sample are unmarried, and 20 of these are living with their families of origin. About half the sample have graduated from high school only. The other half have, in addition, completed some college, but only three have bachelor's degrees. Most of the men in our sample are employed full time in occupations ranging from delivery boy to high-paying managerial positions. Half the men earn less than $5,000. The rest earn from $5,000 to more than $15,000 a year. Nearly all of the parents of these men are married and living together. Three fathers are deceased. Paternal occupations vary from unskilled laborer to professional. The educational level of the fathers also varies, but 14 of 33 have college degrees.

Psychological Test Data

In general, the results of the psychological tests reveal great diversity among individual members and rarely support generalizations about the entire rescue squad.

Although the MMPI profiles of some members could be described as pathological or deviant, there is no evidence of group deviance on any of the MMPI scales. The mean group profile has peaks on "psychopathic deviate" (Pd) and "hypomania" (Ma) and is not remarkable for a population of young men. Considerable efforts did not yield any meaningful subgroups among the profiles.

The Internal-External Control Scale reflects the extent to which the individual sees events in his life as self-determined or as determined by external forces. The squad members showed a wide range of scores from a low (internal) score of 1 to a high (external) score of 17. The mean group score was 7.7, with a standard deviation of 3.5. This mean score is not unusual and, with such great variability in individual scores, gives no evidence of a meaningful group tendency.

The Interpersonal Checklist was used to explore the self-concept of the squad member and to relate his self-concept to his role as a volunteer. Each volunteer was asked to describe himself, his ideal self, and the ideal rescue squad volunteer. The subjects' descriptions of these concepts can be grouped under eight interpersonal themes or styles. The results of this analysis are shown in table 1.

In regard to the ratings of self, the sample shows some diversity. However, 79 percent are described by one of three interpersonal themes: managerial-autocratic, responsible-hypernormal, and competitive-narcissistic. Of more interest are the results for the ratings of the ideal volunteer. Seventy-two percent of the ratings fit the managerial-autocratic theme, an interpersonal approach characterized by tendencies to manage, direct, lead, or guide others or, in the extreme, to dominate others. The second most common theme for the ideal volunteer (noted in only 16 percent of the cases) is responsible-hypernormal, which includes sympathizing, helping, and supporting others or, in the extreme, pitying others and compulsively taking responsibility. The shared view of the ideal volunteer as managerial-autocratic is striking and perhaps is related to the importance of organization and decisive individual action in rescue operations. Obviously, sympathy and the wish to help are not enough in rescue work.

Of interest is the fact that more subjects' ratings of ideal self (61 percent) than of self (38 percent) fit the managerial-autocratic theme. This suggests that the concept of the ideal volunteer may serve as a kind of organizing principle for the squad member's ideal self-concept. Hence success in the rescue squad comes to mean that the individual volunteer approaches more nearly his ideal self. Of course, success in the squad may *result* from change in the individual's self-concept, so that the process is perhaps best viewed as an interaction. This interaction will be illustrated in one of the case reports to follow.

HYPOTHESES AND CASE REPORTS

While the idea that membership in the rescue squad reflects shared personality traits or that it serves similar

TABLE 1

Percentages of Interpersonal Checklist Ratings of Self, Ideal Self, and Ideal Rescue Squad Volunteer Described by Various Themes

Concept	Number	Interpersonal Themes			
		Competitive-Narcissistic	Managerial-Autocratic	Responsible-Hypernormal	All other themes

Ideal self	31	3	61	19	17
Ideal volunteer	25	4	72	16	8

psychological functions for most members is not supported by our data, squad membership may be important for the adaptation of the individual member. The individual case report offers an approach to this question and is used to illustrate certain hypotheses about the adaptive functions of squad membership.

Rescue work as mastery of past traumas. Rescue work requires active, organized coping with the physical trauma of others. Some volunteers might choose such work as a means of dealing with past physical traumas or with the fear of a future trauma to themselves or loved ones.

As a group the squad members had few significant past or current illnesses. Physical trauma due to accidents was much more common. We doubt that the number of accidents is unusual for a population of young men and do not consider our subjects *as a group* to be accident-prone. However, several individuals did describe many accidental injuries and might be considered to be accident-prone.

Since most of the members grew up in the area served by the rescue squad, we wondered how many had themselves been rescued by the squad. For accidents not related to rescue work, 11 subjects were rescued by the squad: five before they were members, five after they joined, and one both before and after he joined.

Case 1. J.F., a 21-year-old married salesman, joined the squad at age 18. He has one older brother who joined the squad before him and influenced him to join. His father was a volunteer fireman, and his mother did volunteer work at various hospitals. Before joining the squad, J.F. had much exposure to squad activities. He knew many members. He was a "dummy" victim for rescue exercises. However, on four occasions he was a real victim for the squad. Most of these involved minor injuries, although the accidents were potentially quite serious. J.F. reported numerous accidents, primarily automobile accidents, all of which occurred prior to his joining the squad.

There is little doubt that the squad plays an important role in J.F.'s life. Despite being married and working full time, he spends an average of 36 hours per week with the squad. J.F.'s avocational interests are rather hazardous: hunting sharks underwater with a spear gun, boar hunting, and car racing.

It is clear that there are multiple determinants in J.F.'s joining and remaining in the squad, but the possible influence of his numerous accidents and regular rescues by the squad prior to his joining is most intriguing. Being in the squad and knowing rescue techniques may offer some security in the hazardous world in which he lives. "[Before I joined the squad] I didn't know enough to be bold enough to go out and try to help somebody, to tell people I'm Larry Lifesaver.... I don't broadcast it now, but should this situation arise.... Well, when your number's up your number's up, but sometimes you can put it off." To support his argument he described how he saved two people from drowning because of the knowledge he had acquired in rescue work. Also, in answer to a question about what he liked about the squad, he said: "Your training can be helpful in later years if someone in your family or near you becomes ill or hurt."

His dangerous hobbies and numerous accidents are highly suggestive of a counterphobic defense against fears of injury and death. Perhaps by dealing over and over with the accidents of *others* in his rescue work, he gains some command of his *own* fears of injury and death. This may have enabled him to give up his pathological counterphobic behavior of putting himself in situations of danger. At least, he has had no accidents in the years since he joined the squad.

Our hypothesis about the possible significance of a past trauma to rescue work also included trauma to or death of loved ones. In this regard one interesting finding emerged. Each case of parental death in our sample (three fathers) had involved rescue attempts by the squad. In two cases the fathers died of heart attacks when the sons were seven and 14 years of age. The third paternal death, from a progressive respiratory disease, occurred when the son was 21 (three years before he joined the squad). One other case of interest is that of a subject whose entire family, including himself, was involved in an automobile accident when he was 11. Unfortunately, we do not have sufficient information on these subjects to explore the connection, if any, between the traumatic incidents and their later participation in volunteer rescue work.

The rescue squad as a social support in the struggle for independence from family. One of the important developmental tasks of the adolescent and young adult is the attainment of independence from his primary family. The rescue squad provides a stable group of peers as well as older male figures and a place to come at any time for companionship. Nearly two-thirds of the men in our sample are still living at home with their parents. The rescue squad seems to function as a social support for some of the volunteers who are struggling to become independent from their families of origin.

Case 2. T.L., an unmarried 21-year-old man, joined the squad at age 17. He works full time as a reporter for a local newspaper. He is an only child and, although financially self-supporting, lives with his parents. He joined the squad in his last year of high school. He recalls that as a child he used to go with his mother to watch the squad play baseball and that she was upset to see some of the members drinking beer. He describes his parents' initial ambivalence about his joining the squad as follows: "When I first came on the squad my parents wanted me to stay only on my duty night. They were a little hesitant even giving permission.... I don't know if it was because they didn't want me out there dealing with people."

On the Interpersonal Checklist he described himself, his ideal self, and the ideal volunteer as responsible-hypernormal. This interpersonal style is characterized by giving help, sympathy, and support to others, or, in the extreme form, by excessive pity and compulsive responsibility. Other data support this view of T.L. For example, in answer to a question about what he liked about being a rescue squad volunteer, he wrote: "Just the general idea that there are many people in the area that get hurt, and someone must want to help and care for these people, and that's what I like to do."

That this is not just a superficial explanation was made clear in the interview and TAT:

> When I first came on the squad I was excited and if I were called now I'd feel the same way.... It's a funny feeling, a tingle that goes through you. Whenever the bell goes off it's a call for help. That's the entire purpose.... Whenever I go on a call I hope that nobody is hurt seriously, but if they are, I know I'll be there to help them.

In response to the blank TAT card, he said:

> Could be a picture of the happiness of a father when he looks into the room to see the child that his wife has just borne ... or you could have a picture of a bad accident such as we had this past week.... The bodies were just strewn across [the road] and you just wonder how this could happen to men. A life is lost, you feel sorry that he or she could have a loved one somewhere, and you almost feel the pain that they have when they find out that the loved one has perished from the earth.

T.L.'s need to feel needed by the squad and by the people he rescues seems basic to his motivation for rescue work. Also, he is struggling to free himself from overinvolvement with his family, especially his mother. He stated: "My mother is always saying she misses me. I tell her they've had me for 21 years. I've got to grow up sometime." Probably the squad is a transitional object for his dependency needs, thus allowing him to become more independent of his parents.

The rescue squad as a school for the development of self-control and competence. The squad appeals to the action-oriented personality. Tremendous importance is placed on the ability to engage in constructive, organized action in the face of major or minor disaster. However, controlled, not impulsive, action is required. For example, rescue vehicles may be driven rapidly with sirens screaming, but carelessness at any time and inappropriate speeding are not condoned. Squad members' eligibility for driving rescue vehicles is regulated by an elaborate system of advancement based on their experience and safety record.

Also, the individual is expected to coordinate his actions with others. A capacity for independent, cooperative individual action is needed; heroic individual action is not expected or even desired. This aspect of the group culture is reflected in the answers given by our sample to a question about the characteristics of a good rescue squad worker. Steadiness and reliability under pressure were ranked as the two most important of seven characteristics; physical strength and coordination and courage were ranked as the two least important.

One open-ended question asked what the volunteer enjoyed most about being on the squad. When these answers were grouped, it was found that helping people in need was the most frequently mentioned factor. Social involvement with other squad members and a feeling of competence from a job well done were the next two most frequent answers. The following case report illustrates the role that the squad may have in providing a socially constructive outlet for action while at the same time enhancing the volunteer's self-esteem and sense of competence.

Case 3. H.S., a 25-year-old recently married college graduate, joined the squad when he was 17. He has steadily moved up the ranks and currently is third captain on the squad. He works as a manager for a large hardware store. H.S. comes from an upper-middle-class family. Currently, he spends about 18 hours per week with the squad. He feels that his relationships with other volunteers are the most enjoyable aspect of being on the squad. Also, he enjoys "belonging to and running one of the best, if not the best, rescue squad in the world." H.S. is highly action-oriented. In answer to a question about his feelings when dealing with injured people, he said, "If you're worth a damn you don't feel anything on calls because you're *doing* things—like a doctor."

Although the significance of rescue squad membership for H.S. is multifaceted, two aspects seem especially important. The squad provides a fraternity-like group of peers, and the rescue work provides an outlet for his need for action and an environment for the development of competence and self-control through organized action.

This case report also illustrates the interaction of self-concept with the group culture of the squad. H.S.'s self-concept fits the competitive-narcissistic theme of the Interpersonal Checklist. The adaptive features of this theme are competitiveness and assertiveness; the maladaptive features are boastfulness and exploitation of others. His concepts of ideal self and ideal volunteer fit the managerial-autocratic theme, which emphasizes leadership and organization. This suggests that the squad culture has perhaps influenced his ideal self-concept. Success in the squad brings him closer to his ideal self. The reverse is also true. As he becomes more like his ideal self, he is more likely to succeed in the squad culture. In any case, the outcome for H.S. would likely be a greater sense of personal control and competence.

DISCUSSION

The question of whether our findings apply to rescue squad volunteers in general could be explored by studying other volunteer rescue squads. However, the general notion that voluntary group membership is an important means of coping for the individual probably holds true for many types of voluntary organizations. The specific

stresses and conflicts as well as the specific coping mechanisms would vary according to the particular organization and individual involved.

General systems theory and the new therapies derived from it have placed emphasis on the current social systems and groups to which the individual belongs. The new field of organizational behavior has given some attention to the relationship between organizational culture and psychological growth (9). Recent interest in the "indigenous therapist" suggests the analogy of the "indigenous group," which may be similar to a therapy group in helping the individual to cope with his problems. Yet a great deal remains to be learned about the interaction between organizational culture and individual adaptation and development. Study of this interaction may have profound implications for preventive psychiatry. For example, an organization such as the rescue squad may provide a socially constructive and growth-enhancing outlet for energetic and action-oriented youth, who otherwise might become alienated from society or engage in antisocial activities.

The contribution of voluntary group membership to the development and adaptation of the individual is an appropriate area for future research, with important implications for various types of therapy and for community consultation.

Political Psychiatry: The Psychiatrist in Elective Public Office

BY EDWARD MESSNER, M.D.

The author attempts to show that elected public officials encounter numerous opportunities for action favoring the prevention of psychiatric disorders and the promotion of mental vigor. He demonstrates that preventive measures are compatible with and usually exemplify discharging the duties of public office thoroughly and effectively. The observations of the author, a psychiatrist who was elected to the school committee in his town, are made from first-hand experience and might be viewed as representing a political microcosm.

NUMEROUS SOCIAL, ECONOMIC, political, and environmental phenomena affect personality development and susceptibility to psychiatric disorders. Many of these phenomena are regulated or influenced by government at local, state, or federal levels.

Governmental decisions are usually based on multiple considerations, but only seldom are they made with explicit concern for their consequences regarding the incidence of psychiatric disorders in the constituency. If these consequences were not only made explicit but were also given high priorities, it seems reasonable to expect that the frequency and severity of some psychiatric conditions might be reduced.

At each level of government in the United States the greatest power is generally vested in elective offices. Elected officials determine public policy and often direct the administration of governmental functions. They are faced on a routine basis with choices that can affect the prevention of psychiatric disorders. While these choices vary in their potential quantitative effect on mental health, each one represents an opportunity, however small, to move in the direction of a healthier society or perhaps of a society of healthier individuals. For elected officials these opportunities are frequent and are very much in the line of official duty. Beyond that, certain opportunities to help prevent psychiatric disorders can be found in some of the unofficial actions that go with public office. These include speeches, news conferences, informal discussions with other officials, and some features of the official's personal conduct.

The influence that one can have on preventive actions varies with the office and with the level of government. The situations I will describe here relate to an elected school committee or board of education and are derived from first-hand experience. I was elected to the school committee of a small town in Massachusetts in February 1971. The population of the town was approximately 12,000 at that time.

Dr. Messner is Clinical Instructor in Psychiatry, Harvard University, Cambridge, Mass. His address is Zero Emerson Place, Boston, Mass. 02114.

OFFICIAL ACTIONS AFFECTING PREVENTION

The broad responsibility of a school committee is to take general charge of the public schools. Foremost among its functions is to develop a curriculum that meets the needs and interests of the students. The school committee can provide special education classes for retarded or emotionally disturbed children and can enrich the regular curriculum in a variety of ways using many techniques, such as complex computer scheduling. For children whose education will stop at the high school level, it can provide courses involving work experience and on-the-job training.

A work-study program requires participation by businesses in the community. Additional integration of the school system with the town at large can be cultivated by recruiting volunteers to help perform many tasks in the school system. This may serve several functions, including the reduction of adolescents' alienation from adults and the converse.

To illustrate some of the interventions available to an elected official, I shall describe some of my own actions. For example, for the sake of economy as well as of integration, I initiated and organized a system of school volunteers. It centers around a committee that attempts to match volunteers and tasks which need to be performed in areas of maintenance, administration, curriculum enrichment, etc. It was accepted officially by the school committee, and many townspeople have come forward to participate.

The school committee has great influence on the objectives, philosophy, and principles of education in the public schools; it can pursue a variety of goals. These can include the encouragement of human compassion, the development of capacities for self-discipline, an understanding of the individual's responsibilities to his family, community, nation, and mankind, and the development of other virtues of maturity.

In taking charge of the public schools the school committee hires teachers, determines various policies involving the conditions of their employment, and influences their professional lives in many ways. Generally, the morale and effectiveness of any group of government employees are factors affecting not only their own mental health, but sometimes the constituency as well. Since

teachers influence students in many ways, appointing capable, mature, creative, and compassionate educators can lead to wholesome influences on the students. Once appointed, they can be helped to function at their best through considerate, reasonable, and respectful behavior by the school committee.

Prior to my election to the school committee, a considerable degree of strife between the committee and the educators had existed. The school committee members had publicly directed many disparaging comments toward the teachers and the administrators. Soon after my election, I proposed, and the committee adopted, a procedure for commending educators and others who performed outstanding work. This served as a clear and practical indication of a quest for harmony and balance.

The school system, through its guidance functions, can detect which children are particularly susceptible to psychiatric conditions. Once the vulnerable individuals are recognized, they can be helped in such ways as appropriate class placements, family conferences, referrals for professional help, etc. The school committee can strengthen and expand these functions.

In a similar vein community organizations like the Parent-Teacher Association, junior baseball leagues, and fraternal organizations can make substantial contributions to the prevention or reduction of delinquency. The school committee can support and encourage these organizations by allowing them to use such school facilities as athletic fields, meeting rooms, auditoriums, and cafeterias.

Wide participation by the individual residents of a community in the workings of its government can also serve a number of preventive functions and can lead to a sense of kinship and fraternity. Such participation can offer hope to members of the community through mutual responsiveness with the agencies of its government. As an important agency of local government, the school committee can encourage public participation in its meetings, welcome and support citizens' advisory groups, and make its deliberations easily accessible to the press. It can promote parent-teacher conferences and the development of adult education programs.

For example, the day after my election I proposed, and the school committee adopted, a policy of publishing the agendas of all official meetings. Later I proposed forming an advisory committee to evaluate all business procedures employed by the school department. The school committee adopted it, and a group of highly competent and respected business leaders volunteered to serve on the advisory committee. I supported a policy of holding school committee meetings in school libraries or cafeterias instead of in the confining office of the superintendent. This made attendance by the press and public a great deal more comfortable than it had been in the past. I also proposed procedures for systematic parent-teacher conferences that have not yet been adopted, and I fostered the establishment of an adult educational program that is nearly self-financing.

An individual member of a school committee cannot determine these objectives and functions single-handedly, although he does have the power and the responsibility to exert direct influence on the choices which that body selects. An individual on a school committee need not be a psychiatrist to be able to make sound decisions. However, most elected officials do not seem to think explicitly about the prevention of psychiatric disorders. Many opportunities for prevention become evident if one is prepared to recognize them.

UNOFFICIAL ACTIONS AFFECTING PREVENTION

An elected official participates in a relationship (which is defined by law) with each of his constituents. Beyond that these relationships extend into emotional areas. Accordingly, he is in a position to affect his constituents, constructively or otherwise, far more than most appointed officials. Elected officials, for example, are open to observation when performing their duties at public meetings of their agencies. A psychiatrist in public office becomes less obscure and therefore less mysterious, and consequently, psychiatry might also become less strange and threatening to the constituency. It is well known that familiarity can breed feelings other than trust. However, if the psychiatrist in public office is accepted as a sincere participant in town affairs and as being genuinely concerned about its problems, then psychiatry might become relatively acceptable by association.

The acceptability of psychiatry in its usual forms is far from being the entire issue when it comes to prevention. From the viewpoint of government, prevention involves a variety of institutions, processes, and groups. Public officials communicate on many occasions with their constituents and with fellow officials to persuade and to influence them, and occasionally to listen to them. Some of these occasions can be used to prevent mental disorders.

The promotion of mental vigor encompasses a wide range of political, economic, and social phenomena that are unrecognizable as applied psychiatry except by one who is specifically seeking them.

Mental vigor requires a reduction of bigotry and of alienation. An example of a group prejudice in an early stage of development recently occurred in my town. A large number of apartment houses were constructed because a new interstate highway had made the town more accessible. Restrictions were minimal because the town had not enacted a zoning law. Over a period of several years repeated attempts to pass a zoning law had been defeated. After the construction of the apartments began, enough voters joined together to pass a zoning law and to defeat the usual attempt to rescind it by referendum. At the same time many residents of the town predicted that the occupants of the apartment houses would swell the school population significantly and that as a result, the costs of educating these students would exceed the property tax revenue to be derived from the new structures.

Feelings of resentment arose against the people who were moving into the apartments. Most of the people came from other communities, but some were individuals who had formerly lived in private dwellings in town. They

were not members of any identifiable ethnic, racial, economic, or religious group.

The "apartment people" were blamed for increases in the tax rate. At the time that this hostility first arose, the tax rate had already increased for various reasons, but this could not realistically be attributed to the apartment houses or to their occupants. The antagonism developed before there was any appreciable enrollment in the schools of pupils from families who had recently moved into the town. A new and potentially disruptive form of prejudice seemed to be developing. It occurred to me to go to the new apartment complexes to try to recruit volunteers for the public school system. I thought that by doing so, I could create an opportunity to invite the new residents of the town to join in a community effort while demonstrating to the others that the newcomers could contribute.

As arrangements for the meeting were developed, the local newspapers announced them in detail. The reporters quoted my views and intentions regarding the divisiveness that was evolving. The weekly newspaper, which is mailed free to every household in the town, printed several stories about this effort. The project was an unofficial individual effort, but I was naturally identified as a member of the school committee. It is my impression that this effort attracted more attention than there would have been had I not been an elected official.

When the meeting actually took place, it was well publicized and an editorial was written about it. The local council of churches became interested and wrote a letter to one of the newspapers supporting the idea of welcoming the newcomers. Later, two church leaders contacted me to discuss the issue; both of them informed me that they spoke for groups of laymen who were getting involved.

Since that time, other individuals and groups have demonstrated an interest in including the newcomers in town activities. Recently, for example, the head of the Red Cross drive asked me to help recruit volunteer workers among the people living in the new apartments. Reports of incidents of hostility and bitterness between old and new residents have subsided. This suggests that the prejudice may have decreased.

DISCUSSION

My experience in government up to now has been extremely encouraging. It has provided evidence that democratic government has great potential for the promotion of mental and emotional vigor. It has indicated that "government of the people, by the people, and for the people," taken in its literal sense, might become the basis for the prevention and reduction of mental, emotional, and behavioral disorders. This experience has directed my attention to the possible value of psychiatric study of elected officials and of the interpersonal processes related to public office. One way to conduct this kind of research would be to study oneself as a participant. Other studies could attempt to delineate the many ways in which elected officials can affect the emotional atmosphere of a community.

The results of these studies might be applied by public officials who are not psychiatrists but who are concerned about mental health. More important, citizens might come to recognize that such concern could be expected and should be demanded of their elected officials. In part this article is an invitation to psychiatrists to consider service as elected public officials. There is much to be learned through direct participation. Moreover, it is rewarding as a personal contribution of one's time, energy, and intelligence to his fellow citizens in a challenging enterprise.

Very few psychiatrists seem to have served in elective office. Those who have served apparently have published very little about their experience. A computer-based survey (1) of 2,300 of the world's biomedical journals, covering a period of three years (January 1968–December 1970), revealed no articles about psychiatrists as candidates for or occupants of elective office. This search was conducted by the Medical Literature Analysis and Retrieval System (MEDLARS), a service of the National Library of Medicine.

Elective office can provide the psychiatrist with a special opportunity to serve his community as a responsible citizen. It can enable him to observe and to participate in varied and complex political interactions. In some instances a psychiatrist's special awareness of developmental and interpersonal processes can direct him to official actions that might serve to prevent or to reduce the incidence of psychiatric disorders. Elective office provides opportunities to examine and to test possibilities of enhancing the mental vigor of a constituency through the medium of the humanistic functioning of its government.

The Euclid House: A Therapeutic Community Halfway House for Prisoners

BY STEWART L. ALEDORT, M.D., AND MORGAN JONES, M.S.W.

Euclid House represents an attempt to create an effective therapeutic community for prisoners in a halfway house staffed almost totally by blacks and by some ex-offenders. This experiment is viewed as a long-term investment in training staff, developing ideas and concepts, and taking chances in order to tap the creativeness of the staff and residents. The ultimate hope is that this model will serve for some prisoners as an alternative to incarceration.

AMERICAN CORRECTIONAL SYSTEMS are currently faced with the task of dealing with 1.3 million offenders every day and of admitting 2.5 million new prisoners each year. They all have problems of overcrowding, underfunding, and a rising prison population. Thirty-three to 50 percent of all released inmates are reimprisoned within five to ten years after their release, often for more serious offenses (1). Despite the difficulties the correctional systems face, some have initiated major changes in the way they accomplish their task. The Federal Bureau of Prisons and the correctional systems of California and of the District of Columbia are examples.

One significant change is the increasing collaboration between the criminal justice systems and the behavioral sciences. As a result, there is a slow but clearly recognizable shift toward rehabilitation as a goal in the psychiatric sense. Aptitude tests, estimates of personality development, ego strengths, and the extent of family and social integration are now useful parameters of the rehabilitation task. Prisoners are now involved in group psychotherapy, family counseling, and occupational rehabilitation within the prison walls.

One of the most significant concepts in prison reform has been the development of halfway houses and work release centers. In these centers prisoners move from the prison to the community in a controlled, work-oriented setting prior to their parole. This paper will deal with Euclid House, one of 13 halfway houses in the Washington, D.C., correctional system. It is operated by the Psychiatric Institute Foundation under contract to the District of Columbia Department of Corrections. The foundation, a nonprofit research and training center affiliated with the Psychiatric Institute of Washington, D.C., has been actively involved for the last four years in training employees of the District of Columbia Department of Corrections to staff their halfway houses. Through this experience the foundation was asked to submit a proposal to operate its own halfway house under a grant to the Department of Corrections. Another major impetus for this type of community involvement came from the Psychiatric Institute hospital staff. Black staff members who had gained training and experience working with white middle-class patients expressed their wish to apply their skills to a black ghetto population. In October 1970, the Euclid House Community Correctional Treatment Center opened its doors.

This paper will describe the operational model of Euclid House: the adaptation of the therapeutic community, the residents, the staffing, and the statistics compiled after one year of operation.

SETTING

Two brownstone row houses were renovated and combined to house the 55 residents of Euclid House. In addition to the sleeping quarters, there are several meeting rooms throughout the four-story house. Euclid House is located in the Cardozo community of northwest Washington, D.C., which was the scene of intensive rioting and destruction in 1968. The area has an almost totally black population, with a small Spanish-speaking minority. It is characterized by a high incidence of crime, drug abuse, and welfare cases. There are intense fluctuations in the level of aggressive and destructive outbursts, usually directed against the community and the police. Prior to the opening of Euclid House, members of its staff investigated community response to its opening. The reaction of the community was remarkable for the lack of overt hostility and repugnance to the idea of 50 to 100 prisoners living in the neighborhood. The ambivalence of community residents was evident when they brought court action in an attempt to prevent the house from opening but then failed to appear at the final hearing. The case was dropped.

STAFF AND UNIQUE OPERATION

The 16-member staff consists of the medical director (a

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this work was done, Dr. Aledort was Medical Director of Euclid House and Professional Associate at the Psychiatric Institute, Washington, D.C.; he is now in private practice at 600 New Hampshire Ave., N.W., Washington, D.C. 20037. Mr. Jones is Clinical Director of Euclid House.

The authors wish to thank the Euclid House staff, Dr. Jack Durell, and Ms. Barbara Aledort for their assistance with this paper.

psychiatrist), clinical director (who holds a master of social work degree), administrator, and 13 male and female mental health technicians with varying degrees of experience. Four of the technicians are ex-offenders without previous mental health training. The staff, with the exception of the medical director, is black.

Euclid House differs significantly from the other community correctional centers in the District of Columbia in the following ways:

1. For the first time a group of mental health professionals is operating such a center on a private, nonprofit basis under contract to a government agency.

2. Intensive group therapy techniques characteristic of a therapeutic community and previously applied only to institutionalized psychiatric patients (2, 3) are applied in-depth to the rehabilitation of prisoners.

3. The primary task of the other halfway houses is to effect the rapid reentry of effective wage earners into the community. As a result, the prisoner's raison d'être in the house revolves around his ability or inability to meet the task. This approach does not take into consideration the prisoner's life history of poor work performance, faulty interpersonal communications, and marked resistance to highly structured task-oriented systems. There is little therapeutic work done in other areas of his life, particularly family and peer interactions, and his stay in the center is relatively short—one or two months.

4. Euclid House attempts to recreate the broader Cardozo community within the house by allowing each man's life-style to flourish. As a result, the man's performance in the house can more accurately determine his ability to survive and negotiate in the community he must reenter.

5. Euclid House is committed to the development of psychiatric community techniques for the treatment of prisoners on a long-term basis, and it sees itself as a training center for the staff, prisoners, and the community.

RESIDENTS

The residents at Euclid House come from Lorton State Reformatory in the Washington, D.C., area. The criteria for selection are that the residents must be within four to six months of parole and not be known drug addicts. However, as a result of thorough urinalysis and history taking, approximately 20 percent of the residents have been found to have various addictions. The prisoners range in age from 18 to 56 years, with a mean of approximately 25 to 30. To this date, 153 men have either passed through or are presently living in Euclid House.

The men characteristically have a history of severe emotional, social, and financial deprivation. They usually come from a family where only one parent was present. They have early arrest records, starting in adolescence and multiplying in adulthood, coincident with a poor work record. They have a marked inability to have long-term relationships with women and other significant people in their lives. They also have poor educational histories, marked by feelings of inadequacy, and extremely poor frustration tolerances, usually masked by a facade of bravado and omnipotence.

Almost without exception, these men use projection and denial in dealing with their anxieties, which usually center around helplessness and dependency needs. The area of strongest anxiety is the recognition of the "little boy in them," the part of them that needs caring, love, attention, and nurturing. The men also share an unconscious wish for imprisonment, which suggests a hostile dependency on an omnipotent, omniscient object (usually mothers or surrogate mothers), which they relate to in a childish, magical, nonnegotiable manner. This pattern is reinforced by the behavior of the mothers and surrogate mothers.

THERAPEUTIC COMMUNITY

The therapeutic community techniques used in psychiatric settings have had to be modified in order to be effective for the prison population of Euclid House. Some of the modifications are as follows:

1. Open confrontations are not restricted to just the area of irresponsible behavior; an attempt is made to confront residents over such issues as fears of creativity, responsibility, and independence. As a result, authority roles are not restricted, but are rotated among staff and house residents, who assume responsibility for running meetings, leading groups, and making decisions. This policy has resulted in a freeing up of the community (staff and prisoners) to hire, fire, and evaluate staff; to decide who returns to prison; and to make rules and guidelines regarding such issues as passes, days off, privileges, and restrictions. The residents' history of learning through previous sadomasochistic behavior is shifting to one of learning through toleration of anxiety in a responsible position.

2. In order to maximize interactions, the house residents meet five times a week in one-hour team meetings. These are run by group leaders, assistant group leaders, and counselors. There are two one-hour community meetings per week, an open community meeting in which members of the Cardozo area can participate, weekly family meetings, meetings for couples and singles groups, and home visits. There are also meetings of black identity awareness groups.

3. The staff and house residents make significant changes in the planning and direction of the house. There have been frequent program evaluations that have led to marked shifts in the basic structure.[1] Team leaders rotate among the teams supervising each other. After one year, assistant team leaders move to other teams in order to enhance the interaction.

[1] Every three months the staff and residents evaluate the relevance of the teams, the community meetings, and the individual performances of the staff. As a result, it was decided to increase community meetings from one to three a week. Also, team meetings have shifted from strictly administrative sessions to therapy sessions, with special tasks emphasized. Team issues include identity awareness, unemployment, and saving money.

4. Obstacles are built into the program in order to intensify the residents' needs to negotiate with the staff. The 4 p.m. team meetings, which are mandatory, were perceived by the residents as an obstacle to their working eight hours a day. As a result, the residents have learned to negotiate with the teams and their employers in order to work six hours a day, on Saturdays and Sundays, or during early morning hours to satisfy the team needs. This has led to increased self-esteem since the residents were able to articulate their needs and use previous skills that did not lead to criminal behavior. Through this technique the men are able to localize their needs, express them appropriately, and negotiate them without regressing to their earlier, self-punitive styles. The work of negotiating their needs is a major therapeutic task, since almost all the prisoners have been consistently unable to articulate and localize their needs to significant people in their lives. Instead, they have acted out to communicate with these people. As the house residents have been able to learn to negotiate their basic needs, the team meetings have slowly shifted from negotiation of administrative issues to therapeutic groups that discuss past events, significant traumata, and affective issues in each man's life.

ISSUES AND PROBLEMS

The following is a brief summary of some of the basic issues that the therapeutic community has dealt with over the last year. The major issue for the staff has been their need, both overt and covert, to believe the residents' wish to be seen as childlike, helpless, and irresponsible. This is the result of the staff's need to be seen as magically omniscient and omnipresent, as the paragon of "the responsible mature adult." This is a "mythical gap."

The staff and residents of Euclid House resisted examining the areas in which they were similar, e.g., criminal behavior, irresponsibility, dependency, and the need to be nurtured. A great deal of work has been done to teach the staff how to say "no" to the residents and to recognize their own criminal activity. As is the style of Euclid House, dramatic events highlighted this issue. Three staff members who were ex-offenders were discharged from the house for extortion, theft, and irresponsible work performance. This is still ongoing work, with the mythical gap slowly closing and the "real gap" being examined. The real gap existing between the staff and residents has to do with levels of expertise and what they can teach each other. The residents can teach the staff about manipulating people, surviving in chaos, and dealing with failure.

The issue of failure is essential to Euclid House. It is seen as the source of experience and learning and represents a commonality in the house. The directors expected and demanded failure from both staff and residents. It was felt that creativity could not flourish unless the community felt that mistakes in judgment and decision making would not be punished and would not reinforce earlier sadomasochistic life-styles. This clearly led to a great deal of anxiety, which was characterized by the community's preferring to let a creative member (one who took chances and risks with his mind) "hang himself." The safer, less creative position of being subservient to the director's plan was acted out by the community. Through staff meetings, the staff recognized their need to be safe and their ambivalence and rage in their chosen dependent positions. They were then able to slowly move from the sadomasochistic learning experience with the residents to a healthier model of mutual learning and empathy. For example, when a resident breaks a rule he is not disciplined by the usual restriction to the house, but, instead, must now spend time relating to the group his current situation and reasons for his behavior.

The residents who on the surface have done the best (satisfied house rules, worked consistently, had "no problems" and become surrogate leaders) have had disastrous outcomes through either escaping before parole or through recidivistic activities. There are two kinds of disasters possible within Euclid House. The more obvious one is a resident who overextends himself and takes chances that cause the community at large to label him as a criminal. The other disaster is the man who refuses to act in the house as he would in the outer community and, as such, negates the learning experience of failure and survival in the house. To support this is the fact that the residents with the best outcome have been those who can acknowledge their failures and act them out within the house without jeopardizing their freedom.

STATISTICS

According to correctional workers, recidivism statistics among paroled prisoners have little validity unless there is at least a three-year follow-up. It is clear that results reflecting one year's experience cannot be considered statistically significant. However, we think it is important to comment on certain trends that are clearly evident within the first year's experience at Euclid House. Of the 153 men who have either passed through the house or are presently living there, 13 (8.5 percent) have been rearrested, 18 (11.7 percent) have escaped permanently, and, on the house staff's request, nine (5.8 percent) have been reimprisoned for various reasons (namely, alcoholism, fighting, and psychotic reactions). In comparison to the statistics cited at the beginning of this paper, these figures are encouraging. However, what is much more significant is the fact that as the program has progressed (from the first six months to the last six months), there has been a marked decrease in the number of escapes and amount of recidivistic activity. For example, the institution of an orientation group for new arrivals has eliminated prisoners' escapes within their first five days in the house. The orientation group gives the new arrivals a common identity as new members, rather than as disoriented members on an ongoing team.

SUMMARY

Euclid House represents an attempt to create an effec-

tive therapeutic community for prisoners in a halfway house setting using a staff that includes black mental health technicians and ex-offenders. This experiment is viewed as a long-term investment in training staff, developing ideas and concepts, and taking chances and risks to tap the creativeness of the staff and residents. New directions are envisioned, such as a training center for law students, graduate students, and medical students; a day-care center run by supervised prisoners for the working mothers in the community; and increased community involvement. The ultimate hope is that this model will serve for some prisoners as an alternative to incarceration.

PSYCHIATRIC MEETINGS IN AUSTRALIA

APA members have been invited to participate in two psychiatric meetings to be held in October in Sydney, Australia. The World Federation for Mental Health (W.F.M.H.) will meet October 8–12 on the theme "Cultures in Collision." There will be five days of scientific sessions. Plenary sessions will focus on the following topics: family and community, mass communications, education, physical environment and mental health, migration and mobility, law and mental health, and religion and social change. Members who wish to present papers should submit summaries to Mrs. Valeria Pratt, Chairman, Scientific Committee, W.F.M.H., 9 Langley St., East Syndey, N.S.W. 2010, Australia.

The theme of the Tenth Annual Congress of the Australian and New Zealand College of Psychiatrists (ANZCP) will be "Youth in the Modern World." In addition to studies on adolescents, special attention will be given to the reactions of parents and teachers to today's youth subcultures. Papers related to adolescence and youth may be submitted. Summaries of papers to be considered should be sent to Dr. Frank Weston, Convenor, Scientific Program Committee, ANZCP, 263 East Terrace, Adelaide, South Australia 5000, Australia.

Further information about the congresses can be obtained from Dr. Alfred Auerback, 450 Sutter St., San Francisco, Calif. 94108.

Motivational Factors in Abortion Patients

BY FRANCIS J. KANE, JR., M.D., PETER A. LACHENBRUCH, PH.D., MORRIS A. LIPTON, M.D., PH.D., AND DAVID BARAM

Ninety-nine single white pregnant women seeking abortion were compared with 79 single nonpregnant women of similar background. Most of the women in both groups were college students. Of the pregnant group, 40 percent were found to have motivational factors that may have influenced the occurrence of the pregnancy, such as guilt over use of contraception, a severe acting-out character disorder, or reactions to loss. Psychological testing showed that the pregnant group rated themselves as more impulsive and as tending to externalize aggression. Knowledge of and access to contraception was similar in the two groups. The authors draw inferences from their study as to the most useful kinds of sex education programs colleges might undertake.

STUDIES OF PREGNANCY in adolescents (1–4) have generally reported low levels of sexual education, an ignorance of sexual physiology, a lack of information about and access to contraception, a lack of conscious wishes to be pregnant, and emotional disturbance focusing on an ambivalent mother-child relationship. Some studies also report that a third of those who became pregnant while unmarried repeated the experience shortly thereafter (5). Unfortunately, almost all of the studies reported are uncontrolled; that is, the sample of patients studied was not matched with a control group to provide comparable data.

The study by Gottschalk and associates (6) is the only one utilizing an unmarried control group in an attempt to evaluate the contribution of personality factors to pregnancy in adolescents. The researchers concluded that among the factors important in causing such pregnancies were experiences that minimized the social taboos with respect to youthful premarital sexual intercourse, such as the relative absence of parental supervision and discipline, and the relative lack of reinforcement of Judeo-Christian ethical codes. There was also suggestive evidence that the relative absence of neurotic anxiety or psychophysiologic menstrual disturbances may predispose to early impregnation and that a biological factor may play a part: the pregnant girls appeared to have started menstruating at an earlier age than the control group.

We have also reported a higher self-rating of neuroticism on psychologic testing among a group of black pregnant adolescents compared with a control group who were not pregnant (7). The study to be reported here is an attempt to evaluate the importance of some of these factors in a group of unmarried women who came to the hospital for an abortion.

METHOD

The locus of this study was the obstetric and gynecologic service of the North Carolina Memorial Hospital in Chapel Hill. From June 1970 through January 1971, patients hospitalized for therapeutic abortions were interviewed prior to the abortion by one of us (F.J.K., Jr.) or by a specially trained research assistant. Patients were interviewed on the afternoon prior to the operative procedure or the afternoon following the injection of hypertonic saline solution but before the occurrence of the abortion.

The initial part of the interview was unstructured; it was aimed at eliciting factors that might have contributed to the occurrence of the pregnancy. Later a more structured interview was administered; it was designed to elicit information on the patients': 1) knowledge about and use of birth control methods, 2) knowledge of the accessibility of contraceptive methods, and 3) reasons for use or nonuse of contraceptive methods. Additional data included age, religion, years of education, occupational status, current living arrangements, whether a parent was absent before the patient was 18 years old, occupation and educational achievement of parents, and self-ratings on a three-point scale of commonly reported menstrual symptoms.

All patients interviewed also filled out a Neuroticism Scale Questionnaire (8), which is a 40-item self-rating instrument that gives a total neuroticism score and scores on four subfactors:

1. Submissiveness versus dominance. Those who score themselves as dominant on this bipolar factor describe themselves as dominant, assertive, and aggressive and indicate a tendency to externalize aggression, while those who score themselves as submissive describe opposite tendencies.

2. Sensitivity versus insensitivity or practicality. High scorers on the sensitivity factor are described as tender minded, sensitive, and fastidious. This dimension has been occasionally called "femininity versus masculinity," and, indeed, male homosexuals score significantly higher

Dr. Kane is Medical Director of DePaul Hospital, 1040 Calhoun St., New Orleans, La. 70118. Drs. Lachenbruch and Lipton are with the University of North Carolina School of Medicine, Chapel Hill, where Dr. Lachenbruch is Professor of Biostatistics and Dr. Lipton is Professor and Chairman of the Department of Psychiatry. Mr. Baram is a second-year medical student at Temple University School of Medicine, Philadelphia, Pa.

than the general male population on this subfactor. Those with low scores tend to be less emotional and to lack artistic interest and sensitivity; they are described as inclined to be practical, tough, hard, and responsible.

3. Depression versus "happy-go-lucky cheerfulness." A person with a high score on this component is described as showing a picture of depression: glum, sober, serious, subdued, and pessimistic. The low-scoring person is cheerful, happy-go-lucky, and likes excitement and social contact. The latter person is also described as tending to be impulsive.

4. Anxiety. The person who scores high on this component has feelings of anxiety, dread, guilt, inferiority, frustration, and loneliness. The low scorer shows an absence of anxiety feelings and symptoms.

This questionnaire, derived from items discriminating neurotics from normals on the 16 Personality Factor Questionnaire (9), has been described as reliable and valid in prior testing of normals and neurotics. Age and education have been shown to cause no significant variance.

In all, 186 patients were interviewed, representing over 80 percent of the abortion patients hospitalized during this period. Only two patients refused to be interviewed; the others were not interviewed because of the absence of the investigators. This report will concern itself with the 99 unmarried white girls who were evaluated. The data from this group will be compared with material gathered by a similar anonymous questionnaire from a group of 79 single girls residing in a college dormitory, who represented an 85 percent return of their sample. In addition to filling out the anonymous questionnaire, all members of the control group filled out a Neuroticism Scale Questionnaire.

The abortion patients were referred from all over the state and were predominantly students. For this reason, a student group at a large state university was thought to be a suitable comparison group, since they too represented all regions of the state.

RESULTS

The two groups were fairly similar as to demographic variables except for education. The average age of the abortion group was 18.9 years, while the comparison group averaged 18.1 years. Only three of the abortion group had ever been married, while one of the control group had been. Nine of the abortion group reported a prior pregnancy, in contrast to one of the comparison group. The abortion group averaged 12.1 years of education as compared to 14.4 years in the control group. Almost 60 percent of the abortion group were college students or had recently finished college. The occupation of the head of the household was a white-collar one in 75 percent of the abortion group, compared to 85 percent in the control group. Analysis of the questionnaire data revealed that the abortion group had a significant difference in loss of one or both parents before the age of 18.

There were no significant differences in expressed religious preference; almost 75 percent of both groups described themselves as Protestants.

In response to close questioning about their knowledge of various types of contraception, more than 90 percent of both groups reported an accurate knowledge of at least three forms of contraception, as well as a fairly good idea of their relative efficacy. The mass media were the most frequently mentioned source of information about contraception in both groups, with school programs second and parents a poor third. Ninety percent or more of both groups also reported a knowledge of where and how to obtain contraceptives; neither group considered access to these methods of contraception any serious problem. The sexual activity of the abortion group (with the exception of a few who claimed that the pregnancy followed a single experience and a small group who were promiscuous) were generally confined to a single partner with whom there was a continuous pattern of sexual experience.

Seventy-seven percent of the abortion group reported no use of contraception prior to the pregnancy, while 82 percent of the sexually active members of the control group (35 percent of the entire group) reported consistent use of contraception. In the abortion group, rhythm was the contraceptive method most often reported as used prior to the occurrence of pregnancy, often in conjunction with the use of condoms or withdrawal by the male partner. Of 27 girls who reported any use of contraception prior to this pregnancy, only four reported use of the pill. Concern about the safety of the pill was not voiced frequently. Consistent use of male contraceptives was reported by only 35 percent of those reporting contraceptive use.

In response to questioning about the reasons for the nonuse of contraceptives, the answer most often given was "inconvenience" (15 percent). Another 15 percent of the group had conscious feelings of guilt about the use of contraception on a systematic basis. One young science student at a nearby university who had ample knowledge about animal and human reproduction answered our queries about her nonuse of contraceptive measures with an irate "What kind of girl do you think I am!" Another university senior had considered going to a physician in her hometown but was unable to do so because of her fear that her mother would find out. (She recognized this as a totally irrational fear since she was of age and knew that she could depend on the doctor's discretion.)

Another 15 percent of the group were clearly suffering from a severe acting-out character disorder, manifested by a rebellious, indifferent attitude toward the examiner, the nursing personnel, and their families, and frequently by a history of a hippie life-style. Many of these young women had left home, discontinued school, and were living with other disaffected youths. Their use of contraception was erratic and their sexual practice impulsive and casual. Sometimes the identity of the man who caused the pregnancy was unknown. Abortion was often seen as a concession to the family.

A third subgroup (ten percent) had a significant incidence of loss preceding the pregnancy. One young woman who was divorced and who had systematically

TABLE 1
Incidence of Menstrual Symptoms in Abortion and Control Groups, in Percentages

Menstrual Symptom	Abortion Group (N=99)	Control Group (N=79)
Irritability	78	78
Severe	7	14
Fatigue	63	60
Severe	4	12
Pain	80	77
Severe	25	30
Breast swelling	56	75
Severe	7	6
Abdominal swelling	70	80
Severe	10	17
Depression	66	74
Severe	11	16
Anxiety	42	39
Severe	10	20

used contraception could not explain her impulsive lack of such use prior to her pregnancy. Further probing revealed a still-birth during her terminated marriage; after mentioning this, she spontaneously wondered whether she was trying to prove something to herself by becoming pregnant again. Another patient reported that her pregnancy had followed a casual sexual experience that occurred shortly after a broken engagement. She had been sexually active during that relationship and had regularly used contraception. Only one patient reported a conscious wish to be pregnant prior to the pregnancy.

Menstrual symptoms (except pain) have been shown in prior studies to correlate with neuroticism. Of seven symptoms evaluated, only one was significantly different between the groups: a lower reporting of breast swelling occurred in the abortion than in the control group. However, the self-reporting of severe symptomatology at the menses revealed that the comparison group showed increased levels of irritability, fatigue, and anxiety; on all but one item, the comparison group reported a greater frequency of severe symptoms. (See table 1.)

On a global rating scale of menstrual distress, six of the comparison group reported that they spent at least one day in bed, while none of the abortion group so reported. Reported age at onset of menses was similar for the two groups.

Analysis of the Neuroticism Scale Questionnaire data revealed that on two of the five factors of the scale there were significant differences. The abortion group showed higher scores on the anxiety factor and also scored significantly higher on the "happy-go-lucky cheerfulness" factor. On total neuroticism, the distribution of scores was very similar; it was in the range of norms for the general population. On only one subfactor did both groups exceed the norms for the test. Both groups rated themselves dominant on the submissive versus dominant factor, indicating a tendency to externalize aggression.

DISCUSSION AND CONCLUSIONS

Our data strongly argue against the claim that lack of information about types of contraception and their efficacy or ease of access to contraceptive measures are major factors in the nonuse of contraception that contribute to the occurrence of a pregnancy. Forty percent of the abortion group revealed easily elicited conscious motivational factors that were significant in the explanation of their nonuse of contraception. Guilt and a fear of discovery related to conscious planning of sexual activity in the premarital state were reported most often.

Bauman (10), in a recently reported study of contraceptive practices among a random sample of undergraduate students at our university, reported similar data. Our comparison group comprised 35 percent nonvirgins, while Bauman's group was 50 percent nonvirgin. Seventy percent of his sample were juniors and seniors, while ours were almost all sophomores. Bauman's group also denied that information about or access to contraceptives was any problem. Among those in his group who were sexually active, only a third always used contraceptives; two-thirds most often favored such less effective contraceptive techniques as condoms (69 percent), withdrawal (67 percent), or rhythm (39.5 percent). Only seven percent reported use of the pill. The reasons most often given for nonuse were: intercourse was not expected (38 percent); intercourse occurred only during "safe" periods (22 percent); intercourse should be spontaneous (33 percent); and it was too embarrassing to obtain contraceptives (16 percent).

Our second subgroup among the abortion patients could be characterized clinically as having severe acting-out character disorders. Pregnancy in such persons is often an expression of hostility toward parents and their mores. This clinical impression is supported by the psychological test materials, which showed that the abortion group rated themselves higher on the "happy-go-lucky cheerfulness" factor, an aspect of which is a tendency toward impulsivity. This tendency, in conjunction with the tendency to externalize aggression, could be seen as making the pregnancy more likely. The increased anxiety ratings in the abortion group are not especially noteworthy, since all of the group were awaiting abortion by operative procedure or after injection of the saline solution.

Another subgroup seemed to be using the pregnancy as an attempt to deal with the narcissistic injury occasioned by a psychological loss—most often in a significant personal relationship. Analysis of our data does not reveal whether this subgroup was related to the subgroup that reported parental loss. A previous study (11) of delinquency in girls, however, noted that such delinquency is frequently sexual and also that there is an increased incidence of broken homes among such a group.

The lessened frequency of reporting severe symptoms at the menses would seem to support the findings of Gottschalk and associates that low menstrual disturbance may predispose to early impregnation. Pain, the one symptom reported in excess by the abortion group, was reported by Coppen and Kessel (12) to be unrelated

to neuroticism. Women with few symptoms at the menses are generally seen as less conflicted about the female psychosexual role and more likely to see pregnancy and motherhood as a source of gratification and self-esteem.

There appears to be little that we as psychiatrists can do to intervene in a preventive way when the pregnancy is the result of an acting-out tendency or when it occurs as a response to psychological loss.

While only 15 percent of our group revealed manifest guilt about sexual activity, the data of Bauman (10) seemed to indicate that perhaps this guilt is more widespread than our figures would suggest. Unfortunately, current programs on college campuses seem focused on the provision of information about contraception. On the basis of our data, we believe that while such programs may be desirable, it is far more important to emphasize counseling and educational efforts directed at the importance of young people making conscious choices about the kinds of relationships they are going to have with one another. This would seem a crucial educational issue for colleges to face, since most students are virgins prior to entering college and many become sexually active in a way that indicates their ambivalence about their sexual activity.
